Chapter 1

Introduction

The study of formal languages and finite-state automata theory is very old and fundamental in theoretical computer science. Regular expressions were introduced by Kleene in 1956 ([Kle56]). Research on the connection between formal languages, automata theory and mathematical logic began in the early 1960's by Büchi ([Büc60]). Good introductions into the theory are [Str94] and [Tho96].

We call languages over finite words the $*$ -languages. Likewise, ω -languages are over infinite words. Words are just sequences of input symbols.

The class of regular $*$ -languages is probably the most well studied language class. Its expressiveness is exactly equivalent to the class of finite-state automata as well as regular expressions. The connection between finite-state automata and regular languages was established by S. C. Kleene in [Kle56]. A more generic concept of finite-state automata, including the non-deterministic case, was introduced by M. O. Rabin and D. Scott in [RS59]. It was inspired as a strict subset of the Turing machine which has infinite many states given by its memory. Such finite-state automata get a sequence of input symbols and change their state on each input symbol. Depending on their state, we say that such automaton accepts a given word. Thus, an automaton is representing a language. And the class of languages given by such finite-state automata is equal to the class of regular languages.

For many applications, less powerful subsets of the regular $*$ -languages are interesting, like starfree $*$ -languages, locally testable $*$ -languages, etc., as well as more powerful supersets, like context-free $*$ -languages.

The research on ω -languages and their connection to finite-state automata began a bit later by Büchi [Büc62] and [Mul63]. As for the $*$ -languages, the most well studied ω -language class are the regular ω -languages. Good introductions into these theories are [Tho90], [Tho10], [Sta97] and [PP04]. In contrast to the finite-word acceptance of automata, one can think of several different infinite-word acceptance conditions which lead to different automata, most importantly the Büchi and Muller automata. A central result by Robert McNaughton in [McN66] is the equivalence of non-deterministic Büchi automata and deterministic Muller automata.

Landweber established a strict hierarchy in [Lan69] on subsets of the regular ω -languages, given by other/simpler infinite-word acceptance conditions in finite-state automata, namely

the E-/A-acceptance condition and deterministic Büchi and co-Büchi automata.

For all types, we can also argue with equivalent language-theoretical operators which operate on a $*$ -language and transform them into an ω -language. We will study the equivalences in more detail. The most important operators are ext , lim , in some way equivalent to E-acceptance and deterministic Büchi acceptance, and boolean combinations of those. For some $*$ -language L , $\text{ext } L$ are all infinite words where some prefix is in L and $\text{lim } L$ are all finite words where infinitely many prefixes are in L .

Depending on the $* \rightarrow \omega$ language operator or the ω -automaton acceptance condition, we get different ω -language classes. This was studied earlier already in detail for the class of regular $*$ -languages. E.g., we get the result that the class of boolean combinations of ext -languages is a strict subset of the class of boolean combinations lim -languages. We write $\text{BC } \text{ext } \mathcal{L}^*(\text{reg}) \subseteq \text{BC } \text{lim } \mathcal{L}^*(\text{reg})$, where $\mathcal{L}^*(\text{reg})$ is the class of regular $*$ -languages. In terms of ω -automata, that is that boolean combinations of E-automata are strictly less powerful than boolean combinations of deterministic Büchi automata. Boolean combinations of deterministic Büchi automata in turn are equivalent to deterministic Muller automata. This is basically Landweber's Theorem from [Lan69]. We can also see that the class of boolean combinations of ext -languages, which can be represented by boolean combinations of E-automata is equivalent to the class of languages which can be recognized by both deterministic Büchi and deterministic co-Büchi automata. This is the result from Staiger and Wagner in [SW74].

When we look at other $*$ -language classes, like piecewise testable $*$ -languages and the different ways to transform them into ω -languages, we can get different results. E.g., $\text{BC } \text{ext } \mathcal{L}(\text{PT}) = \text{BC } \text{lim } \mathcal{L}(\text{PT})$ where $\mathcal{L}(\text{PT})$ denotes the class of piecewise testable languages. This study is the main topic of this thesis. I.e. we try to derive some generic conditions on a $*$ -language class \mathcal{L} under which we get similar statements to the regular $*$ -languages. And we will see many examples where the ω -language classes have different relations to each other than in the regular case.

In chapter 2, we introduce the basic terminology of automata theory and language theory. The class of regular $*$ -languages is introduced. Then, we go forward to the introduction of ω -languages and we define and characterize the class of regular ω -languages. We also introduce all $* \rightarrow \omega$ language operators used in this thesis. The chapter ends with a classification of regular ω -language classes into $\text{ext } \mathcal{L}^*(\text{reg})$, $\text{BC } \text{ext } \mathcal{L}^*(\text{reg})$, $\text{lim } \mathcal{L}^*(\text{reg})$ and $\text{BC } \text{lim } \mathcal{L}^*(\text{reg})$. We see that we have strict inclusions on these ω -language classes. The diagram in section 2.5 visualizes these relations.

In chapter 3, we derive generic conditions for arbitrary $*$ -language classes \mathcal{L} under which we get the same inclusions or even strict inclusions as in the $\mathcal{L}^*(\text{reg})$ case. This is the main foundation of this thesis. The chapter starts with some generic lemmas, then introduces some closure properties on \mathcal{L} which are necessary conditions for many of the theorems.

The chapter ends in section 3.4 with the study of a more specific case of $*$ -language classes: Languages defined as finite unions of equivalence classes of some congruence relation $R \subseteq \Sigma^* \times \Sigma^*$ on words.

Chapter 4 studies concrete well-known $*$ -language classes. We mostly concentrate on subsets of the class of regular languages. We will both study the relations and properties in concrete as well as apply the results from chapter 3. Some of the language classes are defined via congruence relations, e.g. locally testable or piecewise testable languages, so we can apply the results from section 3.4.

Chapter 5 finishes with a conclusion.

Chapter 2

Background results on regular ω -languages

2.1 Preliminaries

We introduce some common terminology used in this thesis.

The set of natural numbers $1, 2, 3, \dots$ is denoted by \mathbb{N} , likewise $0, 1, 2, 3, \dots$ by \mathbb{N}_0 . The set of boolean values, also identified as $\{0, 1\}$, is denoted by \mathbb{B} . $\mathcal{P}(M)$ is the set of all subsets of M , sometimes also written as 2^M , defined as $\{S \mid S \subseteq M\}$. $-M$ denotes all elements which are not in M , defined as $\{x \mid x \notin M\}$ (the superset of M is determined by the context). We denote the cardinality of M by $\#M$ or $|M|$. Likewise, for a sequence s of elements which can be both infinite or finite, the length is denoted by $\#s$ or $|s|$. $s[i]$ denotes the i -th element from s . We start counting at 0, i.e. $s[0]$ is the first element and $s[|s| - 1]$ is the last element. $s[i, j]$ denotes the subsequence of s , starting from the i -th element up to the j -th element, both including. If $i > j$, it represents the empty sequence. If $j > |s|$, it is the subsequence $s[i, |s|]$. Given two functions $f: X \rightarrow Y$, $g: Y \rightarrow Z$, we often leave away parentheses and write $g \circ f$ instead of $g(f(x))$ as long as there is no ambiguity. $\exists n: P(n)$, $\forall n: P(n)$, $\exists^\omega n: P(n)$ are short for "there exists n such that $P(n)$ ", "for all n , it holds $P(n)$ " and "there exists infinitely many n with $P(n)$ " respectively, where $P(n)$ is some statements about n . If the domain of n is not specified, the biggest domain is assumed where $P(n)$ makes sense, which is usually \mathbb{N}_0 .

An **alphabet** is a finite set of **symbols**. We usually denote an alphabet by Σ and its elements by a, b, c, \dots . A finite sequence of elements in Σ is also called a **finite word**, often named u, v, w, \dots . The set of such words, including the **empty word** ϵ , is denoted by Σ^* . Likewise, Σ^+ is the set of non-empty words. Infinite sequences over Σ are called **infinite words**, often named α, β . The set of such infinite words is denoted by Σ^ω .

A subset $L \subseteq \Sigma^*$ is called a **language** of finite words or also called a ***-language**. Likewise, a subset $\tilde{L} \subseteq \Sigma^\omega$ is called an **ω -language**.

A set \mathcal{L} of *-languages is called a ***-language class**. Likewise, a set \mathcal{L}^ω of ω -languages is called a **ω -language class**.

We can **concatenate** finite words with each other and also finite words with infinite words. For languages $L_1 \subseteq \Sigma^*$, $L_2 \subseteq \Sigma^*$, $\tilde{L}_3 \subseteq \Sigma^\omega$, we define the concatenation $L_1 \cdot L_2 :=$

$\{v \cdot w \mid v \in L_1, w \in L_2\}$ and $L_1 \cdot \tilde{L}_3 := \{v \cdot \alpha \mid v \in L_1, \alpha \in \tilde{L}_3\}$. In some cases, we might leave away the concatenation dot and just write $L_1 L_2$ or $L_1 \tilde{L}_3$. Exponentiation of languages is defined naturally: For $L \subseteq \Sigma^*$, we define $L^0 := \{\epsilon\}$ and $L^{i+1} := L^i \cdot L$ for all $i \in \mathbb{N}_0$. The union of all such sets, is called the **Kleene star** operator, defined as $L^* := \bigcup_{i \in \mathbb{N}_0} L^i$. The **positive Kleene star** is defined as $L^+ := \bigcup_{i \in \mathbb{N}} L^i$. The ω -**Kleene star** is defined by $L^\omega := \{w_1 \cdot w_2 \cdot w_3 \cdots \mid w_i \in L, w_i \neq \epsilon\}$.

2.2 The class of regular $*$ -languages

The class of regular $*$ -languages is probably the most well-studied class of languages. In the study of formal language theory, Stephen Cole Kleene introduced this class via **regular sets** in [Kle56].

A **regular expression** is representing such a regular set. It represents a language over an alphabet Σ . Regular expressions are defined recursively based on the ground terms \emptyset , ϵ and a for $a \in \Sigma$ denoting the languages \emptyset , $\{\epsilon\}$ and $\{a\}$. Then, if r and s are regular expressions representing $R, S \subseteq \Sigma^*$, then also $r + s$ (written also as $r|s$, $r \vee s$, $r \cup s$), rs (written also as $r \cdot s$) and r^* are regular expressions, representing $R \cup S$, $R \cdot S$ and R^* . Let $\mathcal{L}^*(\text{RE})$ be the set of languages which can be represented as regular expressions.

Example 2.1. $a(a + b)^*bb$ is a regular expression representing the language $\{a\} \cdot \{a, b\}^* \cdot \{bb\}$. □

We extend these expressions also by $r \wedge s$ (written also as $r \cap s$) and $\neg r$ (written also as $\neg r$), representing the language $R \cap S$ and $\neg R := \{w \in \Sigma^* \mid w \notin R\}$. Some basic result of the study of formal languages, as can be seen in e.g. [Str94], is the equivalence of the class of these extended regular expression languages and $\mathcal{L}^*(\text{RE})$.

Regular languages are also strongly connected to finite-state automata. These are a theoretical description of a machine having a finite number of internal states. These automata operate on a discrete set of input symbols and can change the internal state with each input symbol. Because the number of states is finite, these are strictly less powerful than Turing machines, which have an infinite number of states given by the infinite memory. S.C. Kleene proved in [Kle56] that finite automata can express exactly the class of regular languages. A first generic definition of such automata was given in [RS59].

Also defined first by [RS59] is the **non-deterministic finite-state automaton** (NFA) \mathcal{A} over an alphabet Σ . Formally, such NFA \mathcal{A} is defined by a finite set Q of **states** and a subset $\Delta \subseteq Q \times \Sigma \times Q$ of **transitions**. In most cases we also have an **initial state** $q_0 \in Q$ and a subset $F \subseteq Q$ of **final states**.

We write:

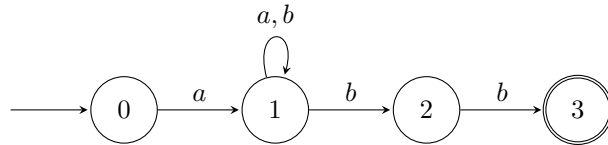

$$\mathcal{A} = (Q, \Sigma, q_0, \Delta, F).$$

A common way to draw such automaton is via a transition graph.

Example 2.2. Let $\Sigma := \{a, b\}$, $Q := \{0, 1, 2, 3\}$, $q_0 := 0$,

$$\Delta := \{(0, a, 1), (1, a, 1), (1, b, 1), (1, b, 2), (2, b, 3)\}$$

and $F := \{3\}$. Then we can draw $\mathcal{A} := (Q, \Sigma, q_0, \Delta, F)$ as:

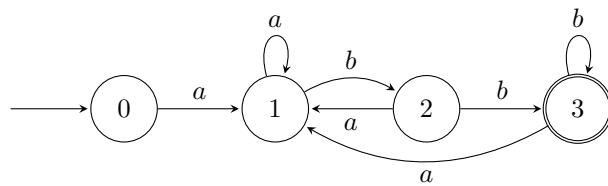

□

The automaton is **deterministic** (a DFA) iff Δ is a subset of a function $Q \times \Sigma \rightarrow Q$. I.e., for every state $q \in Q$ and every $a \in \Sigma$, the following state is determined by Δ or not defined. In that case, we often call the partly-defined function δ and we write

$$\mathcal{A} = (Q, \Sigma, q_0, \delta, F).$$

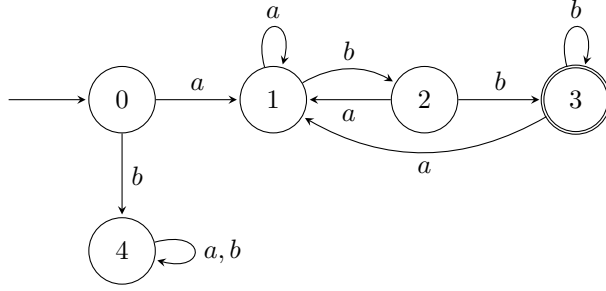

Example 2.3. The following deterministic automaton is in some way (as defined later) equivalent to the non-deterministic automaton from example 2.2:

□

Note that in many cases, as also in example 2.3, δ is only a strict subset of a function, i.e. it is not defined on the whole set $Q \times \Sigma$. We call \mathcal{A} **complete**, if Δ/δ is defined everywhere, i.e. for every state and input symbol, there is a transition defined. If it is not, we can easily extend \mathcal{A} by an additional state, as can be seen in the following example:

Example 2.4. The automaton from example 2.3 is not complete. This is a complete version of the same automaton:

□

Note that we also sometimes have multiple initial states, in which case the automaton is also non-deterministic. Also, in the non-deterministic case, the transition can actual be $\Delta \subseteq Q \times \Sigma^* \times Q$. However, such more generic automaton can be reduced to the definition given here as can be seen in the literature.

Two transitions $(p, a, q), (p', a', q') \in \Delta$ are **consecutive** iff $q = p'$.

A **run** in the automaton \mathcal{A} is a finite sequence of consecutive transitions, written as:

$$q_0 \xrightarrow{a_0} q_1 \xrightarrow{a_1} q_2 \cdots$$

An automaton $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$ **accepts** a finite word $w = (a_0, a_1, \dots, a_n) \in \Sigma^*$ iff there is a run $\rho := q_0 \xrightarrow{a_0} q_1 \xrightarrow{a_1} q_2 \cdots \xrightarrow{a_n} q_{n+1}$ with $q_{n+1} \in F$. We say that the run ρ **matches** the word w . We say that the run is an **accepting run**.

The $*$ -language $L^*(\mathcal{A})$ is defined as set of all finite words which are accepted by \mathcal{A} .

Example 2.5. Let $\Sigma = \{a, b\}$. Let $\mathcal{A}_1 = (Q_1, \Sigma, 0, \Delta_1, F_1)$ be the automaton from example 2.2, $\mathcal{A}_2 = (Q_2, \Sigma, 0, \delta_2, F_2)$ be the automaton from example 2.3 and $\mathcal{A}_3 = (Q_3, \Sigma, 0, \delta_3, F_3)$ be the automaton from example 2.4.

For the finite word $w_1 := aabb \in \Sigma^*$, there are three possible runs in \mathcal{A}_1 :

1. $0 \xrightarrow{a} 1 \xrightarrow{a} 1 \xrightarrow{b} 1 \xrightarrow{b} 1$
2. $0 \xrightarrow{a} 1 \xrightarrow{a} 1 \xrightarrow{b} 1 \xrightarrow{b} 2$
3. $0 \xrightarrow{a} 1 \xrightarrow{a} 1 \xrightarrow{b} 2 \xrightarrow{b} 3$

The third run is an accepting run because $3 \in F_1$. The other two runs are not accepting. Because there is an accepting run, $w_1 \in L^*(\mathcal{A}_1)$.

In \mathcal{A}_2 and \mathcal{A}_3 , w_1 has the deterministic run $0 \xrightarrow{a} 1 \xrightarrow{a} 1 \xrightarrow{b} 2 \xrightarrow{b} 3$. Thus, $w_1 \in L^*(\mathcal{A}_2)$ and $w_1 \in L^*(\mathcal{A}_3)$.

The word $w_2 := aa \in \Sigma^*$ has the only run $0 \xrightarrow{a} 1 \xrightarrow{a} 1$ in \mathcal{A}_1 , \mathcal{A}_2 and \mathcal{A}_3 . Thus, $w_2 \notin L^*(\mathcal{A}_1) \cup L^*(\mathcal{A}_2) \cup L^*(\mathcal{A}_3)$.

The word $w_3 := ba \in \Sigma^*$ has no run at all in \mathcal{A}_1 and \mathcal{A}_2 . This demonstrates that \mathcal{A}_1 and \mathcal{A}_2 are not complete. Thus, $w_3 \notin L^*(\mathcal{A}_1) \cup L^*(\mathcal{A}_2)$. However, it has the run $0 \xrightarrow{b} 4 \xrightarrow{a} 4$ in \mathcal{A}_3 . This run doesn't end in an accepting state and there aren't any other runs because \mathcal{A}_3 is deterministic, thus $w_3 \notin L^*(\mathcal{A}_3)$.

We can see that all automata \mathcal{A}_1 , \mathcal{A}_2 and \mathcal{A}_3 accept exactly the same words, i.e. the same language. In that sense, they are equivalent.

Informally, they all accept the language of words which start with a and end with bb .

A representing regular expression is $a(a + b)^*bb$. □

The class of *-languages accepted by a NFA is called $\mathcal{L}^*(\text{NFA})$. Likewise, $\mathcal{L}^*(\text{DFA})$ is the set of *-languages accepted by a DFA. A basic result (see for example [Str94] or [PP04]) is

$$\mathcal{L}^*(\text{DFA}) = \mathcal{L}^*(\text{NFA}) = \mathcal{L}^*(\text{RE}).$$

This class of *-languages is called the class of **regular *-languages**. We call it $\mathcal{L}^*(\text{reg})$ from now on.

Historically, S.C. Kleene proved in [Kle56] that $\mathcal{L}^*(\text{DFA}) = \mathcal{L}^*(\text{RE})$ and it was shown in [RS59] by M. O. Rabin and D. Scott that $\mathcal{L}^*(\text{DFA}) = \mathcal{L}^*(\text{NFA})$. They also gave an effective procedure to turn a NFA into a DFA, namely the well-known powerset construction. In [Moo56], it was shown that there is an (up to isomorphism) minimal DFA for a language and an algorithm to construct it. This property is nice and powerful because we have a canonical minimal DFA for a given regular language. As we mostly deal with subsets of $\mathcal{L}^*(\text{reg})$ in the rest of this thesis, this minimal DFA is useful in some proofs or definitions as we will see later.

2.3 The class of regular ω -languages

The class of regular ω -languages can be defined in many different ways. We will use one common definition and show some equivalent descriptions.

$$\mathcal{L}^\omega(\text{reg}) := \left\{ \bigcup_{i=1}^n U_i \cdot V_i^\omega \mid U_i, V_i \in \mathcal{L}^*(\text{reg}), n \in \mathbb{N}_0 \right\}$$

This is also called the ω -**Kleene closure** of regular languages.

2.3.1 ω regular expressions

For a regular expression r representing a $*$ -language $R \subseteq \Sigma^*$, we can introduce a corresponding ω regular expression r^ω which represents the ω -language R^ω . This ω regular expression can be combined with other ω regular expressions as usual (via union, intersection and complement) and prefixed by standard regular expressions. We call all these combinations ω regular expressions.

We see that $\mathcal{L}^\omega(\text{reg})$ is closed under union (obviously from the definition), intersection and complement.

Thus, the class of languages accepted by ω regular expressions is exactly $\mathcal{L}^\omega(\text{reg})$.

2.3.2 ω -automata

A different, very common description is in terms of automata.

An automaton $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$ **Büchi-accepts** an infinite word $\alpha = (a_0, a_1, a_2, \dots) \in \Sigma^\omega$ iff there is an infinite run $q_0 \xrightarrow{a_0} q_1 \xrightarrow{a_1} q_2 \xrightarrow{a_2} q_3 \dots$ in \mathcal{A} with $\{i \in \mathbb{N}_0 \mid q_i \in F\}$ infinite, i.e. which reaches a state in F infinitely often.

The language $L^\omega(\mathcal{A})$ is defined as the set of all infinite words which are Büchi-accepted by \mathcal{A} . To make clear that we use the Büchi acceptance condition, we sometimes will also write $L_{\text{Büchi}}^\omega(\mathcal{A})$.

A basic result of the study of this language class is: The set of all languages accepted by a non-deterministic Büchi automaton is exactly $\mathcal{L}^\omega(\text{reg})$ (see [Tho10] or others). Deterministic Büchi automata are strictly less powerful, e.g. they cannot recognise the language $(a + b)^*b^\omega$.

There are some different forms of ω -automata which differ in their acceptance condition. Notable are the **Muller condition**, the **Rabin condition**, the **Streett condition** and the **Parity condition**. With such an acceptance condition, we call it **Muller automaton**, etc. The *main theorem of ω -automata* states:

- Non-deterministic Büchi automata,
- a boolean combination of deterministic Büchi automata,
- deterministic Muller automata,
- deterministic Rabin automata,
- deterministic Streett automata,
- deterministic Parity automata

all recognize the same class of languages. See [Tho10], [Tho96], [PP04] and others. The main part of this theorem is **McNaughton's Theorem** which states the equivalence of non-deterministic Büchi automata and deterministic Muller automata.

Muller automata are interesting for us in the rest of this thesis. The acceptance component of a Muller automaton is a set $\mathcal{F} \subseteq 2^Q$, also called the **table** of the automaton (instead of a single set $F \subseteq Q$). A word $w \in \Sigma^\omega$ is accepted iff there is an infinite run ρ with $\text{Inf}(\rho) \in \mathcal{F}$, where $\text{Inf}(\rho)$ is the set of infinitely often reached states of the run ρ .

We write:

$$\mathcal{A} = (Q, \Sigma, q_0, \Delta, \mathcal{F}).$$

2.3.3 Language operators

Büchi acceptance is closely connected to the language operator

$$\lim(L) := \{\alpha \in \Sigma^\omega \mid \exists^\omega n: \alpha[0, n] \in L\}.$$

We define the language class operator

$$\lim(\mathcal{L}) := \{\lim(L) \mid L \in \mathcal{L}\}.$$

We see that $\lim(\mathcal{L}^*(\text{reg}))$ is equal to the languages accepted by deterministic Büchi automata ([Tho10]). I.e.

$$\lim \mathcal{L}^*(\text{reg}) = \{L_{\text{Büchi}}^\omega(\mathcal{A}) \mid \mathcal{A} \text{ is det. Büchi automaton}\}.$$

Thus,

$$\text{BC} \lim \mathcal{L}^*(\text{reg}) = \mathcal{L}^\omega(\text{reg}),$$

where $\text{BC } \mathcal{X}$ is defined as all **boolean combinations** (union, intersection, complement) from \mathcal{X} . Formally: BC is defined as a function

$$\text{BC}: \mathcal{P}(\mathcal{W}) \rightarrow \mathcal{P}(\mathcal{W})$$

where \mathcal{W} is usually $\mathcal{P}(\Sigma^\omega)$. Then, $\text{BC}(\mathcal{X})$ is defined as the smallest set with

- $\mathcal{X} \subseteq \text{BC } \mathcal{X}$,
- $-X \in \text{BC } \mathcal{X}$ for all $X \in \text{BC } \mathcal{X}$,
- $X_1 \cup X_2 \in \text{BC } \mathcal{X}$ for all $X_1, X_2 \in \text{BC } \mathcal{X}$,
- $X_1 \cap X_2 \in \text{BC } \mathcal{X}$ for all $X_1, X_2 \in \text{BC } \mathcal{X}$.

\mathcal{W} is always determined from the context. We normally have $\mathcal{W} = \mathcal{P}(\Sigma^\omega)$, i.e. the set of all ω -languages. Then, BC is an operator on ω -language classes. We could also have $\mathcal{W} = \mathcal{P}(\Sigma^*)$, then BC would be an operator on $*$ -language classes. Note that we never have $\mathcal{W} = \mathcal{P}(\Sigma^* \cup \Sigma^\omega)$ in this thesis. This note is important as the BC operator would be ambiguous otherwise.

Another classification is

$$\mathcal{L}^\omega(\text{reg}) = \left\{ \bigcup_{i=0}^n U_i \cdot \lim V_i \mid U_i, V_i \in \mathcal{L}^*(\text{reg}), n \in \mathbb{N}_0 \right\}.$$

2.3.4 Logic on infinite words

Let $L_2(\Sigma)$ be the set of formulas $\text{MSO}(<)$ over Σ . The interpretation of such formulas over infinite words is straight-forward. In [Tho81, Theorem 3.1], we can see that

$$\mathcal{L}^\omega(\text{reg}) = \{ A \subseteq \Sigma^\omega \mid A \text{ definable in } L_2(\Sigma) \}.$$

2.3.5 Some properties

Lemma 2.6. $\lim \mathcal{L}^*(\text{reg})$ is closed under intersection.

Proof. In [AH04, Chapter 12, Remark 12.4], this is shown via a special product automata construction of deterministic Büchi automata. □

2.4 Language Operators: Transformation of \ast -languages to ω -languages

We already introduced \lim in section 2.3.3. We can define a family of language operators, partly also derived from the study of $\mathcal{L}^\omega(\text{reg})$. Some of these operators operate on a single language and not on the class. Let \mathcal{L} be a \ast -language class. Let $L \in \mathcal{L}$.

We define the following operators on languages, i.e. $\mathcal{P}(\Sigma^\ast) \rightarrow \mathcal{P}(\Sigma^\omega)$:

1. $\text{ext}(L) := \{\alpha \in \Sigma^\omega \mid \exists n: \alpha[0, n] \in L\} = L \cdot \Sigma^\omega$
2. $\widehat{\text{ext}}(L) := \{\alpha \in \Sigma^\omega \mid \forall n: \alpha[0, n] \in L\}$ (also called the dual-ext)
3. $\lim(L) := \{\alpha \in \Sigma^\omega \mid \forall N: \exists n > N: \alpha[0, n] \in L\} = \{\alpha \in \Sigma^\omega \mid \exists^\omega n: \alpha[0, n] \in L\}$
4. $\widehat{\lim}(L) := \{\alpha \in \Sigma^\omega \mid \exists N: \forall n > N: \alpha[0, n] \in L\}$ (also called dual-lim)

From these, we get operators on language classes ($\mathcal{P}(\mathcal{P}(\Sigma^\ast)) \rightarrow \mathcal{P}(\mathcal{P}(\Sigma^\omega))$) in a canonical way:

1. $\text{ext}(\mathcal{L}) := \{\lim L \mid L \in \mathcal{L}\}$
2. $\widehat{\text{ext}}(\mathcal{L}) := \{\widehat{\text{ext}} L \mid L \in \mathcal{L}\}$
3. $\lim(\mathcal{L}) := \{\lim L \mid L \in \mathcal{L}\}$
4. $\widehat{\lim}(\mathcal{L}) := \{\widehat{\lim} L \mid L \in \mathcal{L}\}$

Note that we sometimes combine those operators via union or intersection, e.g. $\text{ext} \cup \widehat{\text{ext}} \mathcal{L} := \text{ext} \mathcal{L} \cup \widehat{\text{ext}} \mathcal{L}$ or $\text{ext} \cup \lim \mathcal{L} := \text{ext} \mathcal{L} \cup \lim \mathcal{L}$. In many cases, it is also interesting to look at boolean combinations of ω -language classes, i.e.:

1. $\text{BC ext } \mathcal{L} = \text{BC}(\text{ext}(\mathcal{L}))$
2. $\text{BC lim } \mathcal{L} = \text{BC}(\lim(\mathcal{L}))$

In addition, from historical reasons (compare with the definition and alternative characterizations of $\mathcal{L}^\omega(\text{reg})$ in section 2.3), we also have the following other language class operators:

1. $\text{Kleene}(\mathcal{L}) := \left\{ \bigcup_{i=1}^n U_i \cdot V_i^\omega \mid U_i, V_i \subseteq \Sigma^\ast, U_i \cdot V_i^\ast \in \mathcal{L}, n \in \mathbb{N}_0 \right\}$
2. $\text{Lim}(\mathcal{L}) := \left\{ \bigcup_{i=1}^n U_i \cdot \lim V_i \mid U_i, V_i \subseteq \Sigma^\ast, U_i \cdot V_i^\ast \in \mathcal{L}, n \in \mathbb{N}_0 \right\}$

In section 2.3, we have seen that

$$\text{BC lim } \mathcal{L}^*(\text{reg}) = \text{Kleene } \mathcal{L}^*(\text{reg}) = \text{Lim } \mathcal{L}^*(\text{reg}).$$

We mostly concentrate on ext , lim and boolean combinations of them in the rest of this thesis.

For ext and $\widehat{\text{ext}}$, we can also introduce equivalent ω automata acceptance conditions (as in [Tho10]). Let $L \subseteq \Sigma^*$ be a regular $*$ -language and $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$ be an automaton which accepts exactly L . Let $\alpha \in \Sigma^\omega$. Then

- \mathcal{A} **E-accepts** α $:\Leftrightarrow \exists$ infinite run ρ in \mathcal{A} which matches α : $\exists i: \rho[i] \in F$,
- \mathcal{A} **A-accepts** α $:\Leftrightarrow \exists$ infinite run ρ in \mathcal{A} which matches α : $\forall i: \rho[i] \in F$.

We define

$$L_E^\omega(\mathcal{A}) := \{\alpha \in \Sigma^\omega \mid \alpha \text{ is E-accepted in } \mathcal{A}\},$$

$$L_A^\omega(\mathcal{A}) := \{\alpha \in \Sigma^\omega \mid \alpha \text{ is A-accepted in } \mathcal{A}\},$$

and we have the equalities

$$L_E^\omega(\mathcal{A}) = \text{ext}(L),$$

$$L_A^\omega(\mathcal{A}) = \widehat{\text{ext}}(L).$$

Note that \mathcal{A} can be both deterministic or non-deterministic for this property (see lemma 3.2).

In a similar way, the lim operator is equivalent to the Büchi acceptance condition on deterministic automata. Here the determinism matters — non-deterministic Büchi automata are strictly more powerful. For the $\widehat{\text{lim}}$ operator, we can also introduce an equivalent automata acceptance condition: An automaton $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$ **co-Büchi-accepts** an infinite word $\alpha \in \Sigma^\omega$ iff there is a matching infinite run $\rho \in Q^\omega$ such that $\exists N: \forall n \geq N: \rho[n] \in F$.

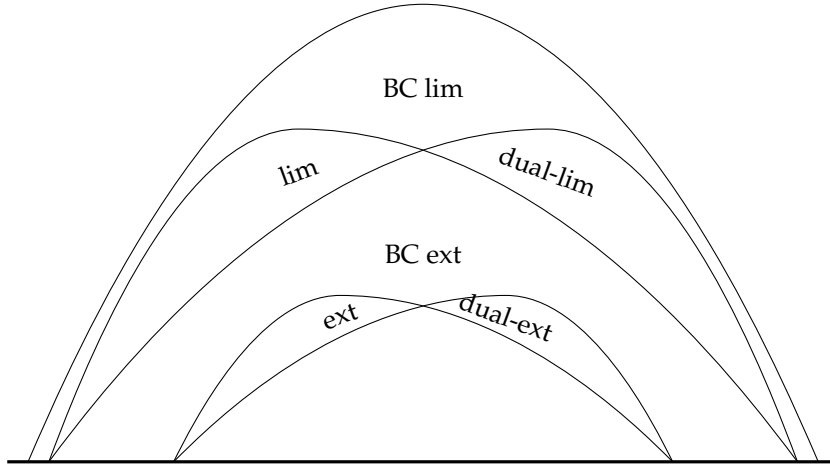

The relations between the E-acceptance / the ext operator or the A-acceptance / the $\widehat{\text{ext}}$ operator with Büchi / lim or co-Büchi / $\widehat{\text{lim}}$ are inspired historically from [Lan69]. Landweber originally introduced the 1,1',2,2',3-acceptance conditions which are equivalent to the E,A,Büchi,co-Büchi and Muller acceptance conditions.

Given these language operators, we are interested in the relations between them. For the class $\mathcal{L}^*(\text{reg})$ of regular languages, we already know that

$$\mathcal{L}^\omega(\text{reg}) = \text{Kleene}(\mathcal{L}^*(\text{reg})) = \text{BC lim}(\mathcal{L}^*(\text{reg})) = \text{Lim}(\mathcal{L}^*(\text{reg})).$$

2.5 Classification of regular ω -languages

Considering $\mathcal{R} := \mathcal{L}^*(\text{reg})$, we get the following language diagram:

where all inclusions are strict. This is basically Landweber's Theorem from [Lan69]. In more detail and a bit extended from Landweber's Theorem:

Theorem 2.7 (Landweber). 1. $\text{ext } \mathcal{R} \cap \widehat{\text{ext } \mathcal{R}} \neq \emptyset$

$$2a. \text{ ext } \mathcal{R} \cap \widehat{\text{ext } \mathcal{R}} \subsetneq \text{ext } \mathcal{R}$$

$$2b. \text{ ext } \mathcal{R} \cap \widehat{\text{ext } \mathcal{R}} \subsetneq \widehat{\text{ext } \mathcal{R}}$$

$$3. \text{ ext } \mathcal{R} \neq \widehat{\text{ext } \mathcal{R}}$$

$$4. \text{ ext } \mathcal{R} \cup \widehat{\text{ext } \mathcal{R}} \subsetneq \text{BC ext } \mathcal{R}$$

$$5. \text{ BC ext } \mathcal{R} = \text{lim } \mathcal{R} \cap \widehat{\text{lim } \mathcal{R}} \text{ (Staiger-Wagner class)}$$

$$6a. \text{ lim } \mathcal{R} \cap \widehat{\text{lim } \mathcal{R}} \subsetneq \text{lim } \mathcal{R}$$

$$6b. \text{ lim } \mathcal{R} \cap \widehat{\text{lim } \mathcal{R}} \subsetneq \widehat{\text{lim } \mathcal{R}}$$

$$7. \text{ lim } \mathcal{R} \neq \widehat{\text{lim } \mathcal{R}}$$

$$8. \text{ lim } \mathcal{R} \cup \widehat{\text{lim } \mathcal{R}} \subsetneq \text{BC lim } \mathcal{R}$$

and we have the additional equalities

$$9. \text{ BC lim } \mathcal{R} = \text{Kleene}(\mathcal{R})$$

10. $\text{BC lim } \mathcal{R} = \text{Lim}(\mathcal{R})$

11. $\text{BC lim } \mathcal{R} = \{L_{\text{Büchi}}^\omega(\mathcal{A}) \mid \mathcal{A} \text{ non-det. automaton so that } L^*(\mathcal{A}) \in \mathcal{R}\}$

Proof. 1. $\tilde{L}_1 := a\Sigma^\omega \in \text{ext} \cap \widehat{\text{ext}} \mathcal{R}$ with $\tilde{L}_1 = \text{ext}(a)$ and $\tilde{L}_1 = \widehat{\text{ext}}(\{\epsilon\} \cup a\Sigma^*)$. ([Tho10, prop, p.38])

2a. $\tilde{L}_{2a} := \text{ext}(a^*b) = a^*b\Sigma^\omega \in \text{ext } \mathcal{R}$. Assume some A-automaton \mathcal{A} with n states accepts \tilde{L}_{2a} . \mathcal{A} would also accept $a^n b^\omega$. I.e. the $(n+1)$ th state after the run of a^n would also accept a , i.e. \mathcal{A} would accept a^{n+1} . By inclusion, \mathcal{A} would accept a^ω . That is a contradiction. Thus, there is no such A-automat. Thus, $\tilde{L}_{2a} \notin \widehat{\text{ext}} \mathcal{R}$.

2b. $\tilde{L}_{2b} := -\tilde{L}_{2a} \in \widehat{\text{ext}} \mathcal{R}$, $\tilde{L}_{2b} \notin \text{ext } \mathcal{R}$.

3. Follows directly from P2a and P2b.

4. $\tilde{L}_4 := \Sigma^* a \Sigma^\omega \cap -(\Sigma^* b \Sigma^\omega)$, $\Sigma = \{a, b, c\}$. Then we have $\tilde{L}_4 \notin \text{ext} \cup \widehat{\text{ext}} \mathcal{R}$, $\tilde{L}_4 \in \text{BC ext } \mathcal{R}$. ([Tho10, p.38])

5. A language in this class is also said to have the **obligation property**. Staiger and Wagner have introduced a **Staiger-Wagner automaton** (also called a **weak Muller automaton**; see definition 3.18) which can accept exactly this language class. This class of languages is called the **Staiger-Wagner-recognizable** languages. This is stated in theorem 3.19.

A generic proof of the equality $\text{BC ext } \mathcal{R} = \lim \mathcal{R} \cap \widehat{\lim} \mathcal{R}$ is given in theorem 3.22.

6a. $\tilde{L}_{6a} := \lim(\Sigma^* a) = (\Sigma^* a)^\omega$. Assume there is $L \subseteq \Sigma^*$ with $\lim(L) = -\tilde{L}_{6a}$. Let $(w_0, w_1, w_2, \dots) \in (\Sigma^*)^\mathbb{N}$ so that $w_0 \in L, w_0 a w_1 \in L, \dots, w_0 \prod_{i=0}^n a w_i \in L \forall n \in \mathbb{N}$. Thus, $\alpha := w_0 \prod_{i \in \mathbb{N}} a w_i \in \lim L$. But $\alpha \notin -\tilde{L}_{6a}$. That is a contradiction. Thus, $-\tilde{L}_{6a} \notin \lim \mathcal{R}$. Because \mathcal{R} is closed under complement, we get $\tilde{L}_{6a} \notin \widehat{\lim} \mathcal{R}$.

6b. Analog to 6a with $\tilde{L}_{6b} := -\tilde{L}_{6a}$.

7. Follows directly from 6a and 6b.

8. $\tilde{L}_8 := (\Sigma^* a)^\omega \cap -(\Sigma^* b)^\omega$. Then $\tilde{L}_8 \notin \lim \cup \widehat{\lim} \mathcal{R}$ but $\tilde{L}_8 \in \text{BC lim } \mathcal{R}$. ([Tho10, prop, p.38])

9.-11. This is explained already in section 2.3 and in more detail in [Tho10] or [Tho81, Theorem 3.1].

□

This relation diagram was studied in detail for $\mathcal{L}^*(\text{reg})$ and the main relations were shown by Landweber in [Lan69]. In addition to the strict inclusions of the expressiveness power of the different automata acceptance conditions, he also showed that it is decidable for a Muller automaton to tell whether its accepted language can also be accepted by an E-/A-/Büchi-/co-Büchi-automaton, respectively.

We are interested whether we get the same properties for other $*$ -language classes under the given language operators.

In chapter 3, we will reformulate many proofs of the properties given in theorem 2.7 in a generic way. The results will give us an understanding about when such ω -language class relations hold, when inclusions are strict and when they are not.

These base theorems are then used in chapter 4 to study some concrete $*$ -language classes.

Chapter 3

General results

In this chapter, we study all the properties, equalities and inclusions from theorem 2.7 for arbitrary $*$ -language classes \mathcal{L} . We try to find necessary conditions such that the inclusions hold and also stay strict. And we demonstrate counter examples when they don't hold anymore or when inequalities become equalities.

We will also study some relations between the ω -language classes constructed from \mathcal{L} with the ω -language classes constructed from $\mathcal{L}^*(\text{reg})$, i.e. the diagram as shown in section 2.5. E.g. we will show that for some cases on \mathcal{L} , we have the equalities $\text{BC lim } \mathcal{L} \cap \text{lim } \mathcal{L}^*(\text{reg}) = \text{lim } \mathcal{L}$ and $\text{BC lim } \mathcal{L} \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}$.

Let \mathcal{L} be a $*$ -language class. We start with some very basic results on language operators.

3.1 Background

We start with some generic properties, equalities and inclusions for the lim and ext operators.

Lemma 3.1. *Let $L, A, B \in \mathcal{L}$.*

1. $\text{ext } L = L \cdot \Sigma^\omega$
2. $\text{ext } L = \text{lim}(L \cdot \Sigma^*)$
3. $\text{ext } L = \widehat{\text{lim}}(L \cdot \Sigma^*)$
4. $-\text{lim}(-L) = \widehat{\text{lim}}(L)$
5. $\widehat{\text{lim}} L \subseteq \text{lim } L$
6. $\text{lim } A \cup \text{lim } B = \text{lim}(A \cup B)$

$$7. \widehat{\lim} A \cup \widehat{\lim} B \subseteq \widehat{\lim}(A \cup B)$$

There is no equality, i.e. ' \supseteq ' does not hold in general.

Proof. 1.-5. They all follow directly from the definition.

6.

$$\begin{aligned} & \alpha \in \lim A \cup \lim B \\ \Leftrightarrow & \exists^\omega n: \alpha[0, n] \in A \vee \exists^\omega n: \alpha[0, n] \in B \\ \Leftrightarrow & \exists^\omega n: \alpha[0, n] \in A \cup B \\ \Leftrightarrow & \alpha \in \lim A \cup \lim B \end{aligned}$$

7.

$$\begin{aligned} & \alpha \in \widehat{\lim} A \cup \widehat{\lim} B \\ \Leftrightarrow & \exists N: \forall n \geq N: \alpha[0, n] \in A \vee \exists N: \forall n \geq N: \alpha[0, n] \in B \\ \Rightarrow & \exists N: \forall n \geq N: \alpha[0, n] \in A \cup B \end{aligned}$$

Consider the languages $A := (aa)^*$, $B := (aa)^*a$. Then,

$$\widehat{\lim}(A \cup B) = \widehat{\lim}(a^*) = a^\omega \neq \emptyset = \emptyset \cup \emptyset = \widehat{\lim} A \cup \widehat{\lim} B.$$

□

For ω automata, we already know that non-determinism can be more powerful than determinism (see section 2.3): The class of non-deterministic Büchi automata can accept clearly more languages than the class of deterministic Büchi automata. E.g. $L^\omega := (a + b)^*b^\omega \in \mathcal{L}^\omega(\text{reg})$ cannot be recognised by deterministic Büchi automata, i.e. $L^\omega \notin \lim \mathcal{L}^*(\text{reg})$.

Luckily, for E- and A-acceptance, this is not the case as we see below. This matches the intuition that E/A-acceptance doesn't really tell something about infinitary properties of words but Büchi/Muller does. And when talking about finite words, we already know that non-deterministic and deterministic automata are equally powerful (see section 2.2).

Lemma 3.2. *The ω -language-class accepted by deterministic E-automata is equal to non-deterministic E-automata. I.e., for every non-deterministic E-automaton, we can construct an equivalent deterministic E-automaton. The same holds for A-automata.*

Proof. Let \mathcal{A}^N be any non-deterministic automaton and \mathcal{A}^D an $(*)$ -equivalent deterministic automaton. Then:

$$\begin{aligned} & \alpha \in L_E^\omega(\mathcal{A}^N) \\ \Leftrightarrow & \exists n: \alpha[0, n] \in L(\mathcal{A}^N) \\ \Leftrightarrow & \exists n: \alpha[0, n] \in L(\mathcal{A}^D) \\ \Leftrightarrow & \alpha \in L_E^\omega(\mathcal{A}^D) \end{aligned}$$

\mathcal{A}^N can be interpreted as an arbitrary E-automata and we have shown that we get an equivalent deterministic E-automata.

For A-automata, the proof is analogous. □

We are interested in relations like $\text{BC ext } \mathcal{L} \stackrel{?}{\subseteq} \text{BC lim } \mathcal{L}$ or $\text{ext } \mathcal{L} \stackrel{?}{\subseteq} \text{lim } \mathcal{L}$. With $\mathcal{L} = \{\{a\}\}$, we realize that even $\text{ext } \mathcal{L} \subseteq \text{lim } \mathcal{L}$ is not true in general ($\text{ext } \{\{a\}\} = \{a\Sigma^\omega\} \neq \emptyset = \text{lim } \{\{a\}\}$). In lemma 3.3, we see a sufficient condition for this property, though.

We want to study all the properties we have shown for $\mathcal{L}^*(\text{reg})$ in theorem 2.7.

We will formulate some properties of interest in a general form for a $*$ -language class \mathcal{L} which all hold for $\mathcal{L}^*(\text{reg})$. We get some general results based on these properties later in this chapter.

Let $L, A, B \in \mathcal{L}$. Then there are the following properties on \mathcal{L} :

1. **Closure under suffix-independence:** $L \cdot \Sigma^* \in \mathcal{L}$

We call L **suffix-independent** iff $L = L\Sigma^*$. However, we are mostly interested in the language class closure.

For language classes defined via subsets of regular expressions, we often can directly check whether we have this closure property. It means that we can add " $\cdot \Sigma^*$ " at the end of a regular expression and we will stay in the same language class. E.g. for the starfree languages (as defined in section 4.1), this is the case.

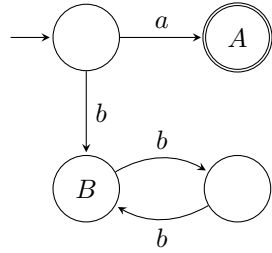

However, this closure is a very strong property as we will see later (e.g. in lemma 3.51). An example of a simple language class which is not closed under suffix-independence is given in example 3.4.

- 2a. **Closure under union:** $A \cup B \in \mathcal{L}$
- 2b. **Closure under intersection:** $A \cap B \in \mathcal{L}$
- 3. **Closure under complementation/negation:** $-L \in \mathcal{L}$
- 4. **Closure under change of final states:** Let $\mathcal{A}_L = (Q, \Sigma, q_0, \delta, F_L)$ be the minimal deterministic automaton for L , i.e. with $L^*(\mathcal{A}_L) = L$. Then, for all $F' \subseteq Q$, we have $L^*((Q, \Sigma, q_0, \delta, F')) \in \mathcal{L}$.

In some proofs, e.g. in theorem 3.22 or lemma 3.25, we have an automaton based on some language of the language class and we do some modifications on it, e.g. we modify the acceptance component.

For $\mathcal{L}^*(\text{reg})$, this closure property holds obviously. For other language classes, it is much less clear. However, we will see a whole class of language classes where this closure property holds, namely the congruence-based language classes as defined in section 3.4. Also, when we have some structure property on the transition graph independent from the final state set for all languages in a class, in many cases it holds that changing the final states keeps the structure property and thus we have the closure under change of final states. An example where we have this is the class of star-free languages (defined in section 4.1) where each minimal deterministic automata is counter-free (see lemma 4.5).

Note that we cannot just take any automaton. For $\mathcal{L}^*(\text{starfree})$ (see section 4.1) and the automaton below, it does not hold:

This is a deterministic automaton for the language $\{a\} \in \mathcal{L}^*(\text{starfree})$. If you make B also a final state, we get the language $a + b(bb)^* \notin \mathcal{L}^*(\text{starfree})$.

- 5. **Closure under alphabet permutation:** For all permutations $\sigma : \Sigma \rightarrow \Sigma$, we have $L_\sigma := \{\sigma(w) \mid w \in L\} \in \mathcal{L}$. (σ on words is defined canonically.)
If $L = L_\sigma$ for all permutations σ , we call L **alphabet permutation invariant**.

3.2 Classification for arbitrary language classes

We will first study $\text{ext } \mathcal{L} \subseteq \text{lim } \mathcal{L}$ inclusions. We have the very simple result:

Lemma 3.3. *If \mathcal{L} is closed under suffix-independence, then*

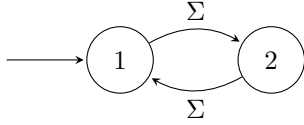

$$\text{ext } \mathcal{L} \subseteq \lim \mathcal{L} \cap \widehat{\lim} \mathcal{L}.$$

Proof. For $L \in \mathcal{L}$, we have $\text{ext } L = L\Sigma^\omega = \lim(L\Sigma^*) = \widehat{\lim}(L\Sigma^*)$. □

However, there is no equivalence. Closure under suffix-independence is a very strong property as can be seen in lemma 3.51.

Example 3.4. *There is a $*$ -language class \mathcal{L} with $\text{ext } \mathcal{L} \subseteq \lim \mathcal{L}$ which is not closed under suffix-independence.*

Proof. Consider the transition graph $\mathcal{A} = (Q, \Sigma, q_0, \delta)$:

Let $\mathcal{L} := \{L^*(\mathcal{A}(F)) \mid F \subseteq Q\}$. I.e. $L_2 := \Sigma(\Sigma\Sigma)^* \in \mathcal{L}$ (all words ending in state 2). Then, $L_2\Sigma^* = \Sigma^+ \notin \mathcal{L}$. I.e. \mathcal{L} is not closed under suffix-independence. However, we have

$$\text{ext } \mathcal{L} = \widehat{\text{ext}} \mathcal{L} = \{\emptyset, \Sigma^\omega\} = \lim \mathcal{L} = \widehat{\lim} \mathcal{L}.$$

□

Lemma 3.5. *If we have $\text{ext } \mathcal{L} \subseteq \lim \mathcal{L}$, then we also have*

$$\text{BC ext } \mathcal{L} \subseteq \text{BC lim } \mathcal{L}.$$

Proof. From $\text{ext } \mathcal{L} \subseteq \lim \mathcal{L}$, it directly follows $\{-\text{ext } L \mid L \in \mathcal{L}\} \subseteq \{-\lim L \mid L \in \mathcal{L}\}$. Thus, it also follows the claimed inequality. □

Lemma 3.6. *If we have $\text{ext } \mathcal{L} \subseteq \lim \mathcal{L}$ and let \mathcal{L} be closed under negation. Then we have*

$$\widehat{\text{ext}} \mathcal{L} \subseteq \widehat{\lim} \mathcal{L}.$$

Proof. Let $L \in \mathcal{L}$. Then $\widehat{\text{ext}} L = -\text{ext}(-L)$. Because of the negation closure, we also have $-L \in \mathcal{L}$ and $\text{ext}(-L) \in \text{ext } \mathcal{L}$.

Thus $\text{ext}(-L) \in \lim \mathcal{L}$. Thus, $\widehat{\text{ext}}(L) = -\text{ext}(-L) \in \{-\lim A \mid A \in \mathcal{L}\} = \{\widehat{\lim A} \mid -A \in \mathcal{L}\}$. Because of the negation closure, we have

$$\{\widehat{\lim A} \mid -A \in \mathcal{L}\} = \{\widehat{\lim A} \mid A \in \mathcal{L}\} = \widehat{\lim} \mathcal{L}.$$

Thus,

$$\widehat{\text{ext}} L \in \widehat{\lim} \mathcal{L}.$$

□

Note that we needed the closure under negation in the proof. This is in contrast to lemma 3.5, where it directly follows. We have to be careful about the inequality

$$\neg \text{ext } \mathcal{L} := \{-\text{ext } L \mid L \in \mathcal{L}\} \neq \widehat{\text{ext}} \mathcal{L}$$

(in general, if \mathcal{L} is not closed under negation).

Analogously:

Lemma 3.7. *If we have $\text{ext } \mathcal{L} \subseteq \widehat{\lim} \mathcal{L}$ and let \mathcal{L} be closed under negation. Then we have*

$$\widehat{\text{ext}} \mathcal{L} \subseteq \lim \mathcal{L}.$$

Proof. Let $L \in \mathcal{L}$. Then $\widehat{\text{ext}} L = -\text{ext}(-L)$. Because of the negation closure, we also have $-L \in \mathcal{L}$ and $\text{ext}(-L) \in \text{ext } \mathcal{L}$.

Thus $\text{ext}(-L) \in \widehat{\lim} \mathcal{L}$. Thus, $\widehat{\text{ext}}(L) = -\text{ext}(-L) \in \{-\widehat{\lim A} \mid A \in \mathcal{L}\} = \{\lim A \mid -A \in \mathcal{L}\}$. Because of the negation closure, we have

$$\{\lim A \mid -A \in \mathcal{L}\} = \{\lim A \mid A \in \mathcal{L}\} = \lim \mathcal{L}.$$

Thus,

$$\widehat{\text{ext}} L \in \lim \mathcal{L}.$$

□

Summerized:

Lemma 3.8. *Let \mathcal{L} be closed under suffix-independence and negation. Then we have*

$$\text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subseteq \text{lim} \cap \widehat{\text{lim}} \mathcal{L}.$$

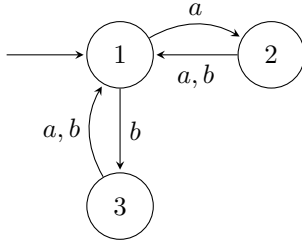

Proof. This is lemma 3.3, 3.6 and 3.7. □

Note that we don't always have $\text{ext} \mathcal{L} \subseteq \text{lim} \mathcal{L}$. For one example with some strict properties see example 3.49. Another example with separates $\text{ext} \mathcal{L}$ and $\text{lim} \mathcal{L}$ even more:

Example 3.9. *There is a $*$ -language class \mathcal{L} , closed under negation, union, intersection and change of final states such that*

$$\text{ext} \mathcal{L} \not\subseteq \text{lim} \mathcal{L}, \quad \text{ext} \mathcal{L} \not\supseteq \text{lim} \mathcal{L}.$$

Proof. Let $\Sigma = \{a, b\}$. Look at the transition graph $\mathcal{A} = (Q, \Sigma, q_0, \delta)$:

Then define $\mathcal{L} := \{L^*(\mathcal{A}(F)) \mid F \subseteq Q\}$. \mathcal{A} is deterministic, thus \mathcal{L} is closed under negation, union, intersection and change of final states.

Let $L_2 := a(\Sigma(b\Sigma)^*a)^* \in \mathcal{L}$ (all words ending in state 2). Then $\text{ext} L_2 = a\Sigma^\omega \notin \text{BC} \text{lim} \mathcal{L}$.

Also, $\text{lim} L_2 = \{\alpha \in \Sigma^\omega \mid \alpha \text{ visits state 2 infinitely often}\} \notin \text{BC} \text{ext} \mathcal{L}$.

In this example, we can see that

$$\text{BC} \text{ext} \mathcal{L} \cup \text{BC} \text{lim} \mathcal{L} \subsetneq \text{BC}(\text{ext} \cup \text{lim}) \mathcal{L}.$$

ω -languages from $\text{BC}(\text{ext} \cup \text{lim}) \mathcal{L}$ express which states will be visited, which will not be visited and which will be visited infinitely often and which not. □

We need the *negation closure* for the natural expected inclusion of the dual operators in their boolean closures.

Lemma 3.10. *Let \mathcal{L} be closed under negation. Then*

$$\text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subseteq \text{BC ext } \mathcal{L},$$

$$\lim \cup \widehat{\lim} \mathcal{L} \subseteq \text{BC lim } \mathcal{L}.$$

Proof. Because of the negation closure, we have

$$\text{BC ext } \mathcal{L} \supseteq \{-\text{ext } A \mid A \in \mathcal{L}\} = \{\widehat{\text{ext}} A \mid -A \in \mathcal{L}\} = \widehat{\text{ext}} \mathcal{L},$$

$$\text{BC lim } \mathcal{L} \supseteq \{-\lim A \mid A \in \mathcal{L}\} = \{\widehat{\lim} A \mid -A \in \mathcal{L}\} = \widehat{\lim} \mathcal{L}.$$

□

Lemma 3.11. • \mathcal{L} closed under union $\Rightarrow \bigcup \text{ext } \mathcal{L} \subseteq \text{ext } \mathcal{L}$.

• \mathcal{L} closed under intersection $\Rightarrow \bigcap \text{ext } \mathcal{L} \subseteq \text{ext } \mathcal{L}$.

Proof. Let $A, B \in \mathcal{L}$. Then we have $\text{ext}(A \cup B) = \text{ext}(A) \cup \text{ext}(B)$ and $\text{ext}(A \cap B) = \text{ext}(A) \cap \text{ext}(B)$. □

We present some common examples which would separate $\text{ext} \cup \widehat{\text{ext}} \mathcal{L}$ from $\text{BC ext } \mathcal{L}$ and similarly $\lim \cup \widehat{\lim} \mathcal{L}$ from $\text{BC lim } \mathcal{L}$.

Example 3.12. Let $\{a, b, c\} \subseteq \Sigma$. Define $L_a := \Sigma^* a$, $L_b := \Sigma^* b$. Let $L_a, L_b \in \mathcal{L}$. Let \mathcal{L} be closed under negation. Then

$$\text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subsetneq \text{BC ext } \mathcal{L},$$

$$\lim \cup \widehat{\lim} \mathcal{L} \subsetneq \text{BC lim } \mathcal{L}.$$

Proof. The inclusion follows from lemma 3.10.

$\tilde{L}_1 := \text{ext}(L_a) \cap -\text{ext}(L_b)$. Then $\tilde{L}_1 \notin \text{ext} \cup \widehat{\text{ext}} \mathcal{L}$ but $\tilde{L}_1 \in \text{BC ext } \mathcal{L}$. (Theorem 2.7)

$\tilde{L}_2 := \lim(L_a) \cap -\lim(L_b)$. Then $\tilde{L}_2 \notin \lim \cup \widehat{\lim} \mathcal{L}$ but $\tilde{L}_2 \in \text{BC lim } \mathcal{L}$. (Theorem 2.7) □

This example can be generalized a bit. We first introduce M -invariance on a language for $M \subseteq \Sigma$.

Definition 3.13. A language $L \subseteq \Sigma^* \cup \Sigma^\omega$ is called **M -invariant** for $M \subseteq \Sigma$ iff for all $w \in \Sigma^* \cup \Sigma^\omega$,

$$w \in L \Leftrightarrow w|_M \in L,$$

where $w|_M$ is the word w with all letters from M removed.

There is always exactly one **maximum invariant alphabet set** $M_m \subseteq \Sigma$ of L such that L is M_m -invariant. Then call $\Sigma - M_m$ the **non-invariant alphabet set of L** .

Definition 3.14. For $L \subseteq \Sigma^* \cup \Sigma^\omega$, $M \subseteq \Sigma$, define

$$L|_M := L \cap (M^* \cup M^\omega).$$

For the final theorem 3.16, we need another small lemma:

Lemma 3.15. Let $L \subseteq \Sigma^*$ and let L be $\{a, b\} \subseteq \Sigma$ invariant. Then

$$\text{ext } L \notin \widehat{\text{ext } \mathcal{L}^*}(\text{reg}) \Rightarrow \text{ext } L|_{\Sigma - \{a\}} \notin \widehat{\text{ext } \mathcal{L}^*}(\text{reg})$$

and

$$\lim L \notin \widehat{\lim \mathcal{L}^*}(\text{reg}) \Rightarrow \lim L|_{\Sigma - \{a\}} \notin \widehat{\lim \mathcal{L}^*}(\text{reg}).$$

Proof. In any automata for L (no matter if L , $\text{ext } L$, $\widehat{\text{ext } L}$, $\lim L$ or $\widehat{\lim L}$), we can assume without restriction that a, b never changes the state and is everywhere accepted. I.e. we always have the transition set $T := \{(q, \{a, b\}) \mapsto q \mid \text{for all states } q\}$. If we restrict L on $\Sigma - \{a\}$, those are all exactly the same automata with the only difference that the transition set becomes $T|_{\Sigma - \{a\}} = \{(q, \{b\}) \mapsto q \mid \text{for all states } q\}$. I.e. the set of possible automata we are interested about is isomorphic in both cases. Thus, saying that there doesn't exist some kind of automata is independent from whether we say it for L or $L|_{\Sigma - \{a\}}$. \square

Theorem 3.16. Let \mathcal{L} be closed under negation and under alphabet permutation. Let $\{a, b, c\} \subseteq \Sigma$. Let there be $L_a \in \mathcal{L}$. Let $\{a\}$ be the non-invariant alphabet set of L_a and let L_a be $\{b, c\}$ -invariant. Then

$$\text{ext } L_a \notin \widehat{\text{ext } \mathcal{L}^*}(\text{reg}) \Rightarrow \text{ext } \cup \widehat{\text{ext } \mathcal{L}} \subsetneq \text{BC ext } \mathcal{L}$$

and

$$\lim L_a \notin \widehat{\lim \mathcal{L}^*}(\text{reg}) \Rightarrow \lim \cup \widehat{\lim \mathcal{L}} \subsetneq \text{BC lim } \mathcal{L}.$$

Proof. Let op be either ext or lim and let $\overline{\text{op}}$ be the dual version of the operator ($\widehat{\text{ext}}$ or $\widehat{\text{lim}}$). Assume that $\text{op } L_a \notin \text{op } \mathcal{L}^*(\text{reg})$.

The inclusion follows from lemma 3.10.

Define $\tilde{L}_a := \text{op } L_a$. Define the alphabet permutation $\sigma := \{a \mapsto b, b \mapsto a\}$. L_a is an alphabet permutation non-invariant language because $\sigma(L) \neq L$. Define $L_b := \sigma(L_a)$. Because of the alphabet permutation closure, $L_b \in \mathcal{L}$ and $\tilde{L}_b := \text{op } L_b \notin \overline{\text{op}} \mathcal{L}^*(\text{reg})$. I.e., $-\tilde{L}_b = \overline{\text{op}}(-L_b) \notin \text{op } \mathcal{L}^*(\text{reg})$. Also, L_b is $\{a, c\}$ -invariant and $\{b\}$ is the non-invariant alphabet set of L_b .

Then,

$$L_\omega := \tilde{L}_a \cap -\tilde{L}_b \in \text{BC op } \mathcal{L}.$$

Assume there is $L \in \mathcal{L}^*(\text{reg})$ such that $\text{op } L = L_\omega$. Then $\text{op } L|_{\Sigma - \{a\}} = \overline{\text{op}} -L_b|_{\Sigma - \{a\}}$. However, because of lemma 3.15, $\overline{\text{op}} -L_b|_{\Sigma - \{a\}} \notin \text{op } \mathcal{L}^*(\text{reg})$. That is a contradiction. Thus, $L_\omega \notin \text{op } \mathcal{L}^*(\text{reg})$.

Assume there is $\bar{L} \in \mathcal{L}^*(\text{reg})$ such that $\overline{\text{op}} \bar{L} = L_\omega$. Then $\overline{\text{op}} \bar{L}|_{\Sigma - \{b\}} = \text{op } L_a|_{\Sigma - \{b\}}$. However, because of lemma 3.15, $\text{op } L_a|_{\Sigma - \{b\}} \notin \overline{\text{op}} \mathcal{L}^*(\text{reg})$. That is a contradiction. Thus, $L_\omega \notin \overline{\text{op}} \mathcal{L}^*(\text{reg})$. \square

The lemma could be generalized even more by using a generic M -non-invariant language $L \in \mathcal{L}$ with $K \subseteq \Sigma$ maximum invariant alphabet set such that $\#K > \#M$.

Definition 3.17. The $L_a \in \mathcal{L}$ from theorem 3.16, i.e. $\{b, c\}$ -invariant with non-invariant alphabet set $\{a\}$, is called \mathcal{L} - $\widehat{\text{ext-ext-separating}}$ if $\text{ext } L_a \notin \widehat{\text{ext}} \mathcal{L}^*(\text{reg})$. L_a is called \mathcal{L} - $\widehat{\text{lim-separating}}$ if $\text{lim } L_a \notin \widehat{\text{lim}} \mathcal{L}^*(\text{reg})$.

Note that theorem 3.16 required the alphabet Σ to have at least 3 symbols. The proof doesn't work if it has only two symbols. Consider the example 3.12 with $L_a := \Sigma^*a$, $L_b := \Sigma^*b$. If we only have $\Sigma = \{a, b\}$, we would have $-\text{ext } L_b = a^\omega \subseteq \text{ext } L_a$. I.e. we would not get the separation in this case.

The **Staiger-Wagner class** of $\mathcal{L}^*(\text{reg})$ is $\text{BC ext } \mathcal{L}^*(\text{reg}) = \text{lim} \cap \widehat{\text{lim}} \mathcal{L}^*(\text{reg})$. We are interested whether we have the same equality for other language classes \mathcal{L} . We will first restate the known result for $\mathcal{L}^*(\text{reg})$ and then study the general case.

Definition 3.18. A **Staiger-Wagner automaton** (also called **weak Muller automaton**) is of the same form $\mathcal{A} = (Q, \Sigma, q_0, \delta, \mathcal{F})$ with acceptance component $\mathcal{F} \subseteq 2^Q$ like a Muller automaton with the acceptance condition that a run ρ in \mathcal{A} is accepting if and only if $\text{Occ}(\rho) := \{q \in Q \mid q \text{ occurs in } \rho\} \in \mathcal{F}$. ([Tho10, Def.61, p.43])

Theorem 3.19 (Staiger and Wagner). *We see that the class of Staiger-Wagner-recognized languages is exactly the class $\text{BC ext } \mathcal{L}^*(\text{reg})$ and also $\lim \cap \widehat{\lim} \mathcal{L}^*(\text{reg})$. And thus:*

$$\text{BC ext } \mathcal{L}^*(\text{reg}) = \lim \cap \widehat{\lim} \mathcal{L}^*(\text{reg}).$$

Proof. See [Tho10, Theorem 63+64, p.44] or the original publication [SW74]. \square

We are now formulating a more general and direct proof for the $\text{BC ext } \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L}$ equality without Staiger-Wagner-automata (where some of the ideas are loosely based on [Tho10, Theorem 63+64, p.44]).

Theorem 3.20. *Let \mathcal{L} be closed under change of final states. Then*

$$\lim \cap \widehat{\lim} \mathcal{L} \subseteq \text{BC ext } \mathcal{L}.$$

Proof. Let $\tilde{L} \in \lim \cap \widehat{\lim} \mathcal{L}$, i.e. there are deterministic automaton \mathcal{A} and $\overline{\mathcal{A}}$ so that $L_{\text{Büchi}}^\omega(\mathcal{A}) = L_{\text{co-Büchi}}^\omega(\overline{\mathcal{A}}) = \tilde{L}$. Let Q, \overline{Q} be the states of $\mathcal{A}, \overline{\mathcal{A}}$. Now look at the product automaton $\mathcal{A} \times \overline{\mathcal{A}} =: \overset{\times}{\mathcal{A}}$ with states $Q \times \overline{Q}$ and final states $F \times \overline{F} \subseteq Q \times \overline{Q}$. $\overset{\times}{\mathcal{A}}$ is also deterministic.

In $\overset{\times}{\mathcal{A}}$, we have

$$\begin{aligned} \alpha &\in \tilde{L} \\ \Leftrightarrow \forall N: \exists n \geq N: \overset{\times}{\rho}(\alpha)[n] &\in F \times \overline{Q} \\ \Leftrightarrow \exists N: \forall n \geq N: \overset{\times}{\rho}(\alpha)[n] &\in Q \times \overline{F} \end{aligned}$$

Look at a strongly connected component (SCC) S in $\overset{\times}{\mathcal{A}}$. We have $S \cap F \times \overline{Q} \neq \emptyset$, iff S accepts. It follows that all states in S are finite states in $\overline{\mathcal{A}}$, i.e. $S \cap Q \times \overline{F} = S$.

Single $\overset{\times}{q} \in \overline{Q}$ which are not part of a SCC can be ignored. For the acceptance of infinite words, only SCCs are relevant. For S , define

$$S_+ := \left\{ \overset{\times}{q} \in \overline{Q} - S \mid \overset{\times}{q} \text{ can be visited after } S \right\}.$$

Then we have

$$\tilde{L} = \bigcup_{\text{SCC } S} \left\{ S \left| \begin{array}{l} S \text{ will be visited,} \\ \text{all states of } S \text{ will be visited forever after some step,} \\ S_+ \text{ will not be visited} \end{array} \right. \right\}.$$

S will be visited: Let *S* exactly be the finite states. This interpreted as an E-automaton \mathcal{A}_S^E is exactly the condition.

Only the allowed states will be visited but nothing followed after *S*: Mark *S* and all states on all paths to *S* as finite states. This as an A-automaton \mathcal{A}_S^A is exactly the condition.

A similar negated condition might be simpler: Let S_+ be exactly the finite states. Interpret this as an E-automaton $\mathcal{A}_{S_+}^E$.

Then we have

$$\begin{aligned} \tilde{L} &= \bigcup_{\text{SCC } S} L_E^\omega(\mathcal{A}_S^E) \cap L_A^\omega(\mathcal{A}_S^A) \\ &= \bigcup_{\text{SCC } S} L_E^\omega(\mathcal{A}_S^E) \cap \neg L_E^\omega(\mathcal{A}_{S_+}^E). \end{aligned}$$

Thus,

$$\tilde{L} \in \text{BC ext } \mathcal{L}^*(\text{reg}).$$

Given the *closure under change of final states*, we have $L^*(\mathcal{A}_S^E), L^*(\mathcal{A}_{S_+}^E) \in \mathcal{L}$, i.e.

$$\tilde{L} \in \text{BC ext } \mathcal{L}.$$

□

Theorem 3.21. *Let \mathcal{L} be closed under suffix-independence, negation, union and change of final states. Then*

$$\text{BC ext } \mathcal{L} \subseteq \lim \cap \widehat{\lim} \mathcal{L}.$$

Proof. With the *closure under suffix-independence*, we get $\text{ext } \mathcal{L} \subseteq \lim \mathcal{L}$ and $\text{ext } \mathcal{L} \subseteq \widehat{\lim} \mathcal{L}$. I.e. $\text{ext } \mathcal{L} \subseteq \lim \cap \widehat{\lim} \mathcal{L}$. Let us show that $\lim \cap \widehat{\lim} \mathcal{L}$ is closed under boolean closure.

Let $\tilde{L}_a, \tilde{L}_b \in \lim \cap \widehat{\lim} \mathcal{L}$, i.e. $\exists L_{a1}, L_{a2}, L_{b1}, L_{b2} \in \mathcal{L} : \tilde{L}_a = \lim L_{a1} = \widehat{\lim} L_{a2}, \tilde{L}_b = \lim L_{b1} = \widehat{\lim} L_{b2}$. Let us show 1. $-\tilde{L}_a \in \lim \cap \widehat{\lim} \mathcal{L}$, 2. $\tilde{L}_a \cup \tilde{L}_b \in \lim \cap \widehat{\lim} \mathcal{L}$.

1. $-\tilde{L}_a = -\lim L_{a1} = \widehat{\lim} -L_{a1}, -\tilde{L}_b = -\widehat{\lim} L_{a2} = \lim -L_{a2}$. With the *closure under negation*, we get

$$-\tilde{L}_a \in \lim \cap \widehat{\lim} \mathcal{L}.$$

2. $\tilde{L}_a \cup \tilde{L}_b = \lim L_{a1} \cup \lim L_{b1} = \lim L_{a1} \cup L_{b1}$ (lemma 3.1). Thus, with *closure under union*, we have

$$\tilde{L}_a \cup \tilde{L}_b \in \lim \mathcal{L}.$$

The $\widehat{\lim} \mathcal{L}$ case is harder. Let $\mathcal{A}_a, \mathcal{A}_b$ be deterministic automaton, so that $L_{\text{Büchi}}^\omega(\mathcal{A}_a) = L_{\text{co-Büchi}}^\omega(\mathcal{A}_a) = \tilde{L}_a, L_{\text{Büchi}}^\omega(\mathcal{A}_b) = L_{\text{co-Büchi}}^\omega(\mathcal{A}_b) = \tilde{L}_b$. Look at the product automaton $\mathcal{A}_a \times \mathcal{A}_b =: \mathcal{A}^\times$. Then we have $L_{\text{Büchi}}^\omega(\mathcal{A}^\times) = L_{\text{co-Büchi}}^\omega(\mathcal{A}^\times) = \tilde{L}_a \cup \tilde{L}_b$.

Thus,

$$\tilde{L}_a \cup \tilde{L}_b \in \widehat{\lim} \mathcal{L}^*(\text{reg}).$$

Again, given the *closure under change of final states*, we have $L^*(\mathcal{A}^\times) \in \mathcal{L}$.

□

Theorem 3.22. *Let \mathcal{L} be closed under suffix-independence, negation, union and change of final states. Then*

$$\text{BC ext } \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L}.$$

Proof. This follows with theorem 3.20 and theorem 3.21. □

We summarize some of the results from this section to represent all of the strict inclusions from the diagram in section 2.5. The diagram is about $\mathcal{L}^*(\text{reg})$ but the following theorem is generic.

In any case for any \mathcal{L} , we obviously have

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \subseteq \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subseteq \text{BC ext } \mathcal{L}$$

and

$$\lim \cap \widehat{\lim} \mathcal{L} \subseteq \lim \cup \widehat{\lim} \mathcal{L} \subseteq \text{BC} \lim \mathcal{L}.$$

Theorem 3.23. *Let \mathcal{L} be closed under suffix-independence, negation, union, change of final states and alphabet permutation. Then we have*

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \stackrel{(1.)}{\subseteq} \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \stackrel{(2.)}{\subseteq} \text{BC} \text{ext} \mathcal{L} \stackrel{(3.)}{=} \lim \cap \widehat{\lim} \mathcal{L} \stackrel{(4.)}{\subseteq} \lim \cup \widehat{\lim} \mathcal{L} \stackrel{(5.)}{\subseteq} \text{BC} \lim \mathcal{L}.$$

If there is a \mathcal{L} -ext- $\widehat{\text{ext}}$ -separating language L_a , the inclusion in (1) and (2) are strict.

If there is a \mathcal{L} -lim- $\widehat{\lim}$ -separating language L'_a , the inclusion in (4) and (5) are strict.

Proof. (1)-strictness follows with the existence of L_a .

(2)-strictness follows with *closure under negation and alphabet permutation*, L_a and theorem 3.16.

(3) follows with *closure under suffix-independence, negation, union and change of final states* and theorem 3.22.

(4)-strictness follows with the existence of L'_a .

(5)-strictness follows with *closure under negation and alphabet permutation*, L'_a and theorem 3.16.

□

Closure under suffix-independence is a very strong property, as can be seen in lemma 3.51. Note that we only needed this property in theorem 3.23 for the $\text{BC} \text{ext} \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L}$ equality. However, without this equality, we don't have an easy connection between $\text{ext} \mathcal{L}$ and $\lim \mathcal{L}$. We can have $\text{ext} \mathcal{L}(\text{finite}) \supseteq \lim \mathcal{L}(\text{finite})$ as can be seen in section 4.7. Or there are even cases where there is no inclusion in any direction, e.g. see example 3.9.

Without the separating languages L_a, L'_a from theorem 3.23, we formulate a bit less restrictive version:

Lemma 3.24. *Let \mathcal{L} be closed under suffix-independence, negation, union, change of final states. Then*

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \subseteq \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subseteq \text{BC} \text{ext} \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L} \subseteq \lim \cup \widehat{\lim} \mathcal{L} \subseteq \text{BC} \lim \mathcal{L}.$$

Proof. The only non-obvious relation is $\text{BC} \text{ext} \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L}$. This follows with theorem 3.22.

□

3.3 Kleene closure

The Kleene language class operator is a bit disconnected from the study so far on ext and lim. For the class of regular $*$ -languages, we have the equality

$$\text{Kleene } \mathcal{L}^*(\text{reg}) = \text{BC lim } \mathcal{L}^*(\text{reg})$$

as it was shown in section 2.3.

We will now study this relation for arbitrary language classes \mathcal{L} .

Lemma 3.25. *Let \mathcal{L} be closed under change of final states. Then*

$$\text{Kleene } \mathcal{L} \subseteq \text{BC lim } \mathcal{L}.$$

Proof. Let $U, V \subseteq \Sigma^*$, $U \cdot V^* \in \mathcal{L}$. Look at the non-deterministic automaton \mathcal{A} defined as:

$$\longrightarrow U \xrightarrow{\epsilon} V \odot$$

Then we have $L_{\text{Büchi}}^\omega(\mathcal{A}) = U \cdot V^\omega$.

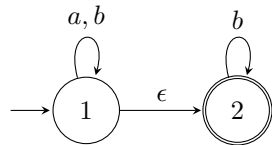

Let us construct deterministic automata for \mathcal{A} so that we can formulate 'V will be visited and not be left anymore' and 'finite states of the V-related automaton will be visited infinitely often' (or ' UV^* will be visited infinitely often').

In a constructed automaton, we must be able to tell whether we are in U or we deterministically have been in U the previous state. In a state power set construction, we can tell whether we are deterministically in U or not. If we are non-deterministic and we may be in both U or V and we get an input symbol which determines that we have been in U , we might not be able to tell from the following power set.

Example:

Let $U = (a + b)^*$, $V = \{b\}$. I.e. $UV^\omega = \{\alpha \in \{a, b\}^\omega \mid \text{at one point in } \alpha, \text{ there are only } bs\}$.

The non-deterministic automaton is:

Powerset construction: The initial state is $\{1, 2\}$. Then we have:

- $\{1, 2\} \xrightarrow{a} \{1, 2\}$
- $\{1, 2\} \xrightarrow{b} \{1, 2\}$

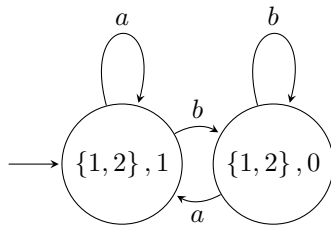

This gives the $*$ -language $\{a, b\}^*$ and we cannot formulate UV^ω in any way from there.

In the construction, when we got the a from $\{1, 2\}$, we knew that we have been deterministically in 1, i.e. in U . We loose this information. To keep it, we introduce another state flag which exactly says wether we have determined that we have been in U . Thus, we construct an automaton with the states $\mathcal{P}(Q) \times \mathbb{B}_{\text{det. been in } U}$, where Q are the states from \mathcal{A} .

For the example, we get the initial state $(\{1, 2\}, 1)$. Then we have:

- $(\{1, 2\}, 1) \xrightarrow{a} (\{1, 2\}, 1)$
- $(\{1, 2\}, 1) \xrightarrow{b} (\{1, 2\}, 0)$
- $(\{1, 2\}, 0) \xrightarrow{a} (\{1, 2\}, 1)$
- $(\{1, 2\}, 0) \xrightarrow{b} (\{1, 2\}, 0)$

This is the automaton

When we mark all states from V and where we have not been deterministically in U as final, this as a co-Büchi automaton gives exactly the condition ‘ $\forall V$ will be visited and not be left anymore’. Let L_E be the $*$ -language of this automata. Note that $L_E \neq UV^*$ in general and esp. in the example.

When we mark the final states as in the original non-deterministic automata, no matter about $\mathbb{B}_{\text{det. been in } U}$, with Büchi-acceptance, we get the condition 'UV* will be visited infinitely often'. This is just $\lim UV^*$.

Together, we get UV^ω , i.e.:

$$\lim UV^* \cap \widehat{\lim L_E} = UV^\omega$$

Given the *closure under change of final states*, we have $L_E \in \mathcal{L}$. Then, it follows

$$\left\{ \bigcup_{i=1}^n U_i \cdot V_i^\omega \mid U_i, V_i \in \mathcal{L} \right\} = \text{Kleene } \mathcal{L} \subseteq \text{BC } \lim \mathcal{L}.$$

□

Lemma 3.26. *Let \mathcal{L} be closed under change of final states. Then*

$$\text{BC } \lim \mathcal{L} \subseteq \text{Kleene } \mathcal{L}.$$

Proof. Let \mathcal{A} be a deterministic Büchi automaton for some language $\tilde{L} = L_{\text{Büchi}}^\omega(\mathcal{A}) \in \mathcal{L}$ with final states F .

For all finite states $q \in F$: If q is not part of a strongly connected component (SCC), we can ignore it. Let S be the SCC where $q \in S$. Then the set of all $\alpha \in \Sigma^\omega$ which are infinitely often in q can be described as $U_q \cdot V_q^\omega$, where U_q is the set of words so that we arrive in q and V_q is the set of words so that we get from q to q . Both sets are obviously regular and because of the *closure of change of final states*, we have $U_q V_q^* \in \mathcal{L}$.

Thus,

$$\tilde{L} = L_{\text{Büchi}}^\omega(\mathcal{A}) = \bigcup_{q \in F} U_q V_q^\omega.$$

Obviously, the Kleene-Closure is closed under union.

TODO: Show that Kleene-Closure is closed under negation. (S306.5) (Follows with non-det Büchi complementation but a more generic proof might be useful.) □

3.4 Congruence based language classes

3.4.1 Introduction

Definition 3.27. We define $\mathcal{L}(R)$ for an equivalence relation $R \subseteq \Sigma^* \times \Sigma^*$

$$\mathcal{L}^*(R) := \{L \subseteq \Sigma^* \mid L \text{ is finite union of } R\text{-equivalence-classes}\}.$$

Examples of such language classes are n -locally testable (LT_n , section 4.4), k, r -locally threshold testable (LTT_r^k , section 4.5) or n -piece-wise testable (PT_n , section 4.3) languages. The exact definition is given in their related section. At their definition, the word-relation basically tells whether a local test / piece-wise test can see a difference between two words.

If a language class $\mathcal{L}(R)$ is defined as finite union of equivalence classes of a relation $R \subseteq \Sigma^* \times \Sigma^*$ and

- the set of equivalent classes of R is finite,
- R is a congruence relation, i.e. also $(v, w) \in R \Leftrightarrow (va, wa) \in R \quad \forall a \in \Sigma$

then we can construct a canonical deterministic automaton \mathcal{A}_R which has $S_R := \Sigma^*/R$ as states, $\langle \epsilon \rangle_R$ is the initial state and the transitions are according to concatenation. Call this an R -automaton.

The LT_n , LTT_r^k and PT_n language classes have the above properties and thus such related canonical automaton.

The set of all such R -automata, varying in the final state set, is isomorphic to $\mathcal{L}(R)$. We have

$$\mathcal{L}^*(R) = \{L^*(\mathcal{A}_R(F)) \mid F \subseteq S_R\} =: \mathcal{L}^*(\mathcal{A}_R).$$

Obviously, by construction, such language classes are all *closed under change of final states*. Obviously, $\mathcal{L}^*(R)$ is also closed under *negation, union and intersection* (via negating, merging or intersecting the final state set of related automata). *Closure under suffix-independence* doesn't directly follow from this — we see some counter example later.

Definition 3.28. Analogously for ω , we get the set of R -E-automata with the ω -language-class

$$\mathcal{L}_E^\omega(\mathcal{A}_R) := \{L_E^\omega(\mathcal{A}_R(F)) \mid F \subseteq S_R\},$$

R -Büchi-automata and

$$\mathcal{L}_{\text{Büchi}}^\omega(\mathcal{A}_R) := \{L_{\text{Büchi}}^\omega(\mathcal{A}_R(F)) \mid F \subseteq S_R\},$$

R -Muller-automata and

$$\mathcal{L}_{\text{Muller}}^\omega(\mathcal{A}_R) := \{L_{\text{Muller}}^\omega(\mathcal{A}_R(\mathcal{F})) \mid \mathcal{F} \subseteq 2^{S_R}\}.$$

Definition 3.29. Analogously to $\mathcal{L}(R)$, for a congruence relation $\tilde{R} \subseteq \Sigma^\omega \times \Sigma^\omega$, define the ω -language-class

$$\mathcal{L}^\omega(\tilde{R}) := \left\{ \tilde{L} \subseteq \Sigma^\omega \mid \tilde{L} \text{ is finite union of } \tilde{R}\text{-equivalence-classes} \right\}.$$

For a relation R on Σ^* , there are various ways to construct a relation on Σ^ω . For now, we mainly study $\widehat{\text{ext}} R$, i.e.

$$(\alpha, \beta) \in \widehat{\text{ext}} R \iff \forall n: (\alpha[0, n], \beta[0, n]) \in R.$$

3.4.2 Classification

With this preparation, we get some obvious results:

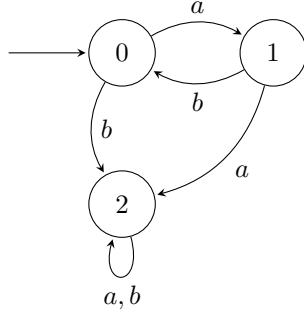

Lemma 3.30. $\mathcal{L}(R)$ is closed under negation, union, intersection and change of final states.

Proof. The closure under negation, union, intersection follows directly from negation, union and intersection of the final state set in R -automata.

For any language $L \in \mathcal{L}(R)$, the minimal deterministic automaton \mathcal{A}_L is a subset of an R -automaton. Thus, any change of final states can be transferred to the R -automaton and we stay in the language class. I.e. $\mathcal{L}(R)$ is closed under change of final states. \square

Example 3.31. There is an R such that $\mathcal{L}(R)$ is *not* closed under suffix-independence.

Proof. Look at the transition graph over $\Sigma := \{a, b\}$:

Define the congruence relation $R \subseteq \Sigma^* \times \Sigma^*$ as $(v, w) \in R \iff v, w$ end up in the same state. Then, the above transition graph is exactly the R -automaton.

If 1 is the only final state, this is the language $L_1 = a(ba)^*$. With suffix independence, we get the language $L_1 \cdot \Sigma^* = a\Sigma^*$.

$a\Sigma^* \notin \mathcal{L}(R)$, thus $\mathcal{L}(R)$ is not closed under suffix-independence.

Furthermore, $\text{ext } L_1 = a\Sigma^\omega$. Marking 0 or 1 as final state in a R -Büchi-automaton accepts the language $\tilde{L}_1 := \{(ab)^\omega\}$. Marking 2 as final state accepts the language $\tilde{L}_2 := (ab)^*(b|aa)\Sigma^\omega$. Then, $\lim \mathcal{L}(R) = \{\emptyset, \tilde{L}_1, \tilde{L}_2, \tilde{L}_1 \cup \tilde{L}_2\}$. And we have $\text{ext } L_1 \notin \lim \mathcal{L}(R)$. But we also have $\tilde{L}_1 \notin \text{ext } \mathcal{L}(R)$. \square

In the rest of this section, we show some equalities:

- $\mathcal{L}_E^\omega(\mathcal{A}_R) = \text{ext } \mathcal{L}(R)$ (lemma 3.32)
- $\mathcal{L}_{\text{Büchi}}^\omega(\mathcal{A}_R) = \lim \mathcal{L}(R)$ (lemma 3.33)
- $\mathcal{L}_{\text{Muller}}^\omega(\mathcal{A}_R) = \text{BC } \lim \mathcal{L}(R)$ (lemma 3.34)
- $\mathcal{L}^\omega(\widehat{\text{ext } R}) = \text{BC } \text{ext } \mathcal{L}(R)$ (lemma 3.35)
- $\text{BC } \lim \mathcal{L}(R) \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}(R)$ (lemma 3.36)

We will see that all those equations hold for all R , i.e. also for $\mathcal{L}(\text{LT}_n)$, $\mathcal{L}(\text{LTT}_r^k)$ and $\mathcal{L}(\text{PT}_n)$.

Note that we still don't necessarily have $\text{ext } \mathcal{L}(R) \subseteq \lim \mathcal{L}(R)$. The example 3.9 also applies here.

We will also see that

$$\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(R)$$

is not always the case. We will give an alternative characterization of this property (theorem 3.47).

Again, a bit more special is the relation

$$\lim \mathcal{L}(R) \cap \widehat{\lim} \mathcal{L}(R) = \text{BC ext } \mathcal{L}(R)$$

(theorem 3.50).

Lemma 3.32.

$$\mathcal{L}_E^\omega(\mathcal{A}_R) = \text{ext } \mathcal{L}(R)$$

Proof. Let $L = \bigcup_i \langle w_i \rangle_R, L \in \mathcal{L}(R)$. Then

$$\begin{aligned} L^\omega &= \text{ext } L \\ \Leftrightarrow L^\omega &= \left\{ \alpha \in \Sigma^\omega \mid \exists n: \alpha[0, n] \in \bigcup_i \langle w_i \rangle_R \right\} \\ \Leftrightarrow L^\omega &= \{ \alpha \in \Sigma^\omega \mid \exists n: \delta_{\mathcal{A}_R}(\alpha[0, n]) \in \{ \langle w_i \rangle_R \subseteq S_R \mid i \} \} \\ \Leftrightarrow L^\omega &= L^\omega(\mathcal{A}_R^E(\{ \langle w_i \rangle_R \subseteq S_R \mid i \})) \end{aligned}$$

□

Lemma 3.33.

$$\mathcal{L}_{\text{Büchi}}^\omega(\mathcal{A}_R) = \lim \mathcal{L}(R)$$

Proof. Let $L = \bigcup_i \langle w_i \rangle_R, L \in \mathcal{L}(R)$. Then

$$\begin{aligned} L^\omega &= \lim L \\ \Leftrightarrow L^\omega &= \left\{ \alpha \in \Sigma^\omega \mid \exists^\infty n: \alpha[0, n] \in \bigcup_i \langle w_i \rangle_R \right\} \\ \Leftrightarrow L^\omega &= \{ \alpha \in \Sigma^\omega \mid \exists^\infty n: \delta_{\mathcal{A}_R}(\alpha[0, n]) \in \{ \langle w_i \rangle_R \subseteq S_R \mid i \} \} \\ \Leftrightarrow L^\omega &= L^\omega(\mathcal{A}_R^{\text{Büchi}}(\{ \langle w_i \rangle_R \subseteq S_R \mid i \})) \end{aligned}$$

□

Lemma 3.34.

$$\mathcal{L}_{Muller}^\omega(\mathcal{A}_R) = \text{BC lim } \mathcal{L}(R)$$

Proof. Any $L^\omega \in \text{BC lim } \mathcal{L}(R)$ can be described by $\text{BC } 2^{S_R}$. $2^{2^{S_R}}$ is also finite. Thus, any $A \in \text{BC } 2^{S_R}$ can be represented in $2^{2^{S_R}}$. This is exactly an acceptance condition in Muller. \square

Lemma 3.35.

$$\mathcal{L}^\omega(\widehat{\text{ext}} R) = \text{BC ext } \mathcal{L}(R)$$

Proof. We want to compare the equivalence classes $\Sigma^\omega / \widehat{\text{ext}}(R)$ with Σ^* / R .

TODO...

\square

When we compare the outer $\text{ext } \mathcal{L}^*(\text{reg})$ (inside $\text{BC lim } \mathcal{L}^*(\text{reg})$, i.e. all regular ω -languages) which is clearly a superset of $\text{ext } \mathcal{L}$ and the inner whole class $\text{BC lim } \mathcal{L}$, a natural question is whether $\text{BC lim } \mathcal{L} \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}$. This is the case for $\mathcal{L}(R)$ as shown below.

Lemma 3.36.

$$\text{BC lim } \mathcal{L}(R) \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}(R)$$

Proof. We have $\text{ext } \mathcal{L}(R) \subseteq \text{ext } \mathcal{L}^*(\text{reg})$ and $\text{ext } \mathcal{L}(R) \subseteq \text{BC lim } \mathcal{L}(R)$. Thus, " \supseteq " is shown.

Now, we show " \subseteq ". Let $L^\omega \in \text{BC lim } \mathcal{L}(R) \cap \text{ext } \mathcal{L}^*(\text{reg})$. Because $L^\omega \in \text{ext } \mathcal{L}^*(\text{reg})$, there is an E-automaton \mathcal{A}^E which accepts L^ω . We can assume that \mathcal{A}^E is deterministic (with lemma 3.2).

We must find an R -E-automaton which accepts L^ω . We will call it the $\overline{\mathcal{A}}^M$ E-automaton and will construct it in the following.

Let \mathcal{A}^M be the deterministic R -Muller-automaton for L^ω (according to section 3.4.1 and lemma 3.34). Without restriction, there are no final state sets in \mathcal{A}^M which are not loops. Then, $\overline{\mathcal{A}}^M$ has the same states and transitions as \mathcal{A}^M .

Look at a final state q^E of \mathcal{A}^E . Without restriction, we can assume that there is no path that we can reach multiple final states at once. Let L_{q^E} be all words which reach q^E exactly once at the end.

Let $w \in L_{q^E}$. Let q be the state in \mathcal{A}^M which is reached after w . Let S be the set of states in \mathcal{A}^M which can be reached from q .

Then, \mathcal{A}^M accepts all words in $L_q \cdot L_{q,S}^\omega$, where L_q is the set of words to q and $L_{q,S}^\omega$ is the set of words of possible infinite postfixes after q in S so that they are accepted. Any word with a prefix in L_q , which is not in $L_q \cdot L_{q,S}^\omega$, will not be accepted by \mathcal{A}^M because \mathcal{A}^M is deterministic. Also, because $L_{q^E} \cap L_q \neq \emptyset$ and $L_{q^E} \cdot \Sigma^\omega \subseteq L^\omega$ and $L_q \cdot L_{q,S}^\omega \subseteq L^\omega$, we get $L_{q,S}^\omega \neq \emptyset$.

Assuming $L_{q,S}^\omega \neq \Sigma^\omega$. Then we would have $L^\omega \notin \text{ext } \mathcal{L}^*(\text{reg})$, which is a contradiction. I.e. $L_{q,S}^\omega = \Sigma^\omega$.

Thus, \mathcal{A}^M accepts all words in $L_q \cdot \Sigma^\omega$. Mark q as a final state in $\overline{\mathcal{A}}^M$. Thus, $\overline{\mathcal{A}}^M$ E-accepts all words in $L_q \cdot \Sigma^\omega \subseteq L^\omega$.

Because we did this for all final states in \mathcal{A}^E , there is no $\alpha \in L^\omega$ which is not accepted by $\overline{\mathcal{A}}^M$. I.e., the R -E-automata $\overline{\mathcal{A}}^M$ accepts exactly L^ω . I.e. $L^\omega \in \text{ext } \mathcal{L}(R)$. \square

In fact, we actually have shown $\text{BC } \lim \mathcal{L} \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}$ for any $\mathcal{L} \subseteq \mathcal{L}^*(\text{reg})$.

We are also interested in the equality $\text{BC } \lim \mathcal{L} \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}$ for some *-language class $\mathcal{L} \subseteq \mathcal{L}^*(\text{reg})$. This is a connection between the outer $\lim \mathcal{L}^*(\text{reg})$ (inside $\text{BC } \lim \mathcal{L}^*(\text{reg})$) which is clearly a superset of $\lim \mathcal{L}$ and the inner whole class $\text{BC } \lim \mathcal{L}$. It turns out that this is not always the case and not as straightforward as in the ext case in lemma 3.36.

We have $\lim \mathcal{L} \subseteq \lim \mathcal{L}^*(\text{reg})$ and $\lim \mathcal{L} \subseteq \text{BC } \lim \mathcal{L}$. Thus, " \supseteq " does hold in all cases.

Example 3.37. *The equality does not hold for any \mathcal{L} .*

Proof. Let $\Sigma = \{a, b\}$,

$$L_a := (b^*a^+)(b^+a^+)^*, \quad L_b := b^*(a^+b^+)^* \quad \text{and} \quad \mathcal{L} := \{L_a, L_b\}.$$

Then, $\lim L_a$ is the set of words where a occurs infinitely often and $\lim L_b$ is the set of words where b occurs infinitely often. Then, $L_\omega := \lim L_a \cap \lim L_b \in \text{BC } \lim \mathcal{L}$. Also, let

$$L_{ab} := (a^*b^+a)^*.$$

Then, $\lim L_{ab}$ is the set of words where both a and b occurs infinitely often. Thus, $\lim L_{ab} = L_\omega$. Obviously, we also have $L_{ab} \in \mathcal{L}^*(\text{reg})$. Thus, $L_\omega \in \text{BC } \lim \mathcal{L} \cap \lim \mathcal{L}^*(\text{reg})$. But we can also see that $L_\omega \notin \lim \mathcal{L}$. \square

Thus, we need some conditions on \mathcal{L} for the equality. Here, we will study the class $\mathcal{L}(R)$. We will introduce a property on $\mathcal{L}(R)$ where we can show the equality. The idea of this property is coming from the study of this equality in terms of automata. Let $L_\omega \in \text{BC lim } \mathcal{L}(R)$. Then there is a representing R -Muller-automaton \mathcal{A}_M for L_ω . Let also $L_\omega \in \text{lim } \mathcal{L}^*(\text{reg})$. Then there is representing deterministic Büchi automaton \mathcal{A}_r for L_ω . We want to show that $L_\omega \in \text{lim } \mathcal{L}(R)$. I.e. we are searching for a representing deterministic automaton whose language is in $\mathcal{L}(R)$ and where the Büchi-acceptance gives us L_ω . Because the R -Büchi-automaton is the canonical deterministic Büchi automaton for $\mathcal{L}(R)$, we must be able to construct such R -Büchi-automaton \mathcal{A}_B for L_ω . Let us look at the product automaton $\mathcal{A}_M \times \mathcal{A}_r$ and determine from there the final state set of \mathcal{A}_B . \mathcal{A}_M already has the right transition graph. \mathcal{A}_r has the Büchi acceptance. So, when looking at the product automaton, we try to find the loops in \mathcal{A}_M which match a final state in \mathcal{A}_r . \mathcal{A}_r might be bigger than \mathcal{A}_M and it doesn't seem clear whether the Muller final state sets of \mathcal{A}_M can be translated to a Büchi final state set. However, when we say that each SCC in \mathcal{A}_M has exactly one loop, there is no inconclusiveness about whether there is a Büchi final state in this SCC in \mathcal{A}_B or not. We will formulate this formally below. So, if we have that property on \mathcal{A}_M , i.e. on $\mathcal{L}(R)$, we can construct \mathcal{A}_B and thus we have the equality.

Definition 3.38. For $\alpha \in \Sigma^\omega$, let $\vec{\alpha} \in (\Sigma^*/R)^\omega$ be the state sequence we run through with α and thus $\text{Inf}(\vec{\alpha}) \subseteq \Sigma^*/R$ those states which are visited infinitely often.

If for every $L \in \mathcal{L}(R)$, there is an inclusion function $B_L: \Sigma^*/R \rightarrow \mathbb{B}$ such that for every $\alpha \in \Sigma^\omega$, we have

$$\alpha \in L \iff \exists q \in \text{Inf}(\vec{\alpha}): B_L(q) = 1.$$

Also, for every $s \notin \text{Inf}(\vec{\alpha})$,

$$B_L(s) = B_L(q) \quad \forall q \notin \text{Inf}(\vec{\alpha})$$

and

$$B_L(s) \neq B_L(q) \quad \forall q \in \text{Inf}(\vec{\alpha}).$$

If such B_L always exists, we call \mathcal{L} **infinity-postfix-independent**.

This definition is as general as possible. It is also well defined if there are an infinity number of equivalence classes of R . Thus, $\mathcal{L}(R)$ doesn't need to be regular. Also, in that case, there might be an $\alpha \in \Sigma^\omega$ with $\text{Inf}(\vec{\alpha}) = \emptyset$.

If $\mathcal{L}(R)$ is regular and we look at an R - ω -automaton, it basically says that when we visit some state infinitely often, it determines in what loop we are and we cannot switch the loop. Formally:

Lemma 3.39. *Let R be a congruence relation with a finite number of equivalence classes. $\mathcal{L}(R)$ is infinity-postfix-independent exactly if and only if every SCC Q in the R -automata (as defined in section 3.4.1) has exactly one looping subset, i.e. Q itself is the only loop in Q .*

Proof. $S_R := \Sigma^*/R$ are the states of the R -automata. Let $Q \subseteq S_R$ be any SCC. Let $\tilde{L} \in \text{BC lim } \mathcal{L}(R)$. Let \mathcal{A}_M be the R -Muller-automaton accepting \tilde{L} .

' \Rightarrow ': Let $\mathcal{L}(R)$ be *infinity-postfix-independent*. Then, for L , we have an inclusion function $B_L: S_R \rightarrow \mathbb{B}$. If there is an accepting loop $Q' \subseteq Q$ in \mathcal{A}_M , it means that every $\alpha \in \tilde{L}$ which ends up in Q' is accepted, thus there is a $q' \in Q'$ with $B_L(q') = 1$. Because we can loop through all of Q and thus construct $\beta \in \Sigma^\omega$ with $\text{Inf}(\vec{\beta}) = Q$, we get $B_L(q) = 1$ for all $q \in Q$. Thus, all possible loops in Q will accept. This was general for any SCC and any language $\tilde{L} \in \text{BC lim } \mathcal{L}(R)$. Because this is a Muller-automaton, this can only be if Q itself is the only loop. Otherwise we can have both an accepting loop and a non-accepting loop in Q which is a contradiction.

' \Leftarrow ': The SCC Q has exactly one looping subset. This is Q itself. Assuming Q is accepting in \mathcal{A}_M . Then define $B_L(q) = 1$ for all $q \in Q$, otherwise $B_L(q) = 0$. This $B_L: S_R \rightarrow \mathbb{B}$ has the needed properties, thus $\mathcal{L}(R)$ is *infinity-postfix-independent*. \square

For piecewise testable languages, this is the case. See section 4.3.

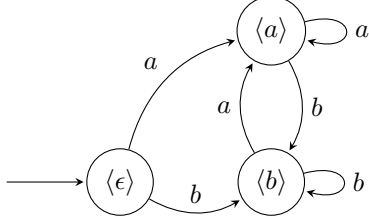

For locally testable languages, this is *not* the case. Depending on the ending of $\alpha[0, n]$, we can switch through different equivalence classes and visit different loops. See section 4.4.

Example 3.40. *There is an R so that $\mathcal{L}(R)$ is not infinity-postfix-independent and*

$$\text{BC lim } \mathcal{L}(R) \cap \text{lim } \mathcal{L}^*(\text{reg}) \neq \text{lim } \mathcal{L}(R).$$

Proof. If we take the example 3.37: For $v, w \in \{a, b\}^*$, let $v =_R w \Leftrightarrow v, w$ end up with the same symbol. I.e., the equivalence classes are $\langle \epsilon \rangle, \langle a \rangle, \langle b \rangle$.

The R -automata is

From example 3.37, we have $L_a = \langle a \rangle$ and $L_b = \langle \epsilon \rangle \cup \langle b \rangle$ and $\mathcal{L} = \{L \in \mathcal{L}(R) \mid \#L = \infty\}$ (only the infinity $L \in \mathcal{L}(R)$ matter for \lim). We also see from the R -automata that there is no way to mark states as final states for Büchi-acceptance so that we get the condition “both a and b occur infinitely often”. Via Muller, we just mark the loop $\{\langle a \rangle, \langle b \rangle\}$ as final. I.e. $\lim L_{ab} \notin \lim \mathcal{L}(R)$ but $\lim L_{ab} \in \text{BC} \lim \mathcal{L}(R)$ and as shown in example 3.37, $\lim L_{ab} \in \lim \mathcal{L}^*(\text{reg})$. Thus, $\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) \neq \lim \mathcal{L}(R)$. \square

This example can actually be extended to be the $\mathcal{L}(LT_2)$ class and generalized to any $\mathcal{L}(LT_n)$. I.e. for all $n \in \mathbb{N}$, $\mathcal{L}(LT_n)$ is not *infinty-postfix-independent* and

$$\text{BC} \lim \mathcal{L}(LT_n) \cap \lim \mathcal{L}^*(\text{reg}) \neq \lim \mathcal{L}(LT_n).$$

When studying the *infinty-postfix-independence* property in more detail, we get the surprising result:

Lemma 3.41. *Let R be a congruence relation with a finite number of equivalence classes. Let $\mathcal{L}(R)$ be infinity-postfix-independent. Then*

$$\text{BC} \lim \mathcal{L}(R) = \lim \mathcal{L}(R).$$

Proof. $S_R := \Sigma^*/R$ are the states of the R -automata. Let $Q \subseteq S_R$ be any SCC. Let $\tilde{L} \in \text{BC} \lim \mathcal{L}(R)$. Let \mathcal{A}_M be the R -Muller-automaton accepting \tilde{L} .

For L , we have an inclusion function $B_L: S_R \rightarrow \mathbb{B}$. If there is an accepting loop $Q' \subseteq Q$ in \mathcal{A}_M , it means that every $\alpha \in \tilde{L}$ which ends up in Q' is accepted, thus there is a $q' \in Q'$ with $B_L(q') = 1$. Because we can loop through all of Q and thus construct $\beta \in \Sigma^\omega$ with $\text{Inf}(\vec{\beta}) = Q$, we get $B_L(q) = 1$ for all $q \in Q$. Thus, all possible loops in Q will accept. In an R -Büchi-automata \mathcal{A}_B , we can mark all states of Q as final states. This was for any SCC Q ,

thus \mathcal{A}_B will accept exactly iff \mathcal{A}_M accepts. Thus we have $\tilde{L} \in \lim \mathcal{L}(R)$. This was for any \tilde{L} , i.e. $\text{BC} \lim \mathcal{L}(R) = \lim \mathcal{L}(R)$. \square

Lemma 3.42. *Let R be a congruence relation with a finite number of equivalence classes. Let $\mathcal{L}(R)$ be infinity-postfix-independent. Then*

$$\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(R).$$

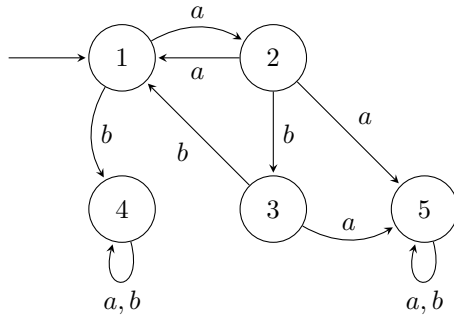

Proof. In lemma 3.41, we showed that we have $\text{BC} \lim \mathcal{L}(R) = \lim \mathcal{L}(R)$. Because $\lim \mathcal{L}(R) \subseteq \lim \mathcal{L}^*(\text{reg})$, we directly get the claimed equality. \square

The question arises whether *infinity-postfix-independence* on $\mathcal{L}(R)$ is equivalent to the equality $\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(R)$. We have shown in lemma 3.39 that if $\mathcal{L}(R)$ is not *infinity-postfix-independent*, there must be a SCC $Q \subseteq S_R$ with more than one loop.

Example 3.43. *There is a congruence relation R with a finite number of equivalence classes where $\mathcal{L}(R)$ is not infinity-postfix-independent but we still have*

$$\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(R).$$

Proof. Look at the fully connected transition graph over $\Sigma := \{a, b\}$:

Define the congruence relation $R \subseteq (\Sigma^*, \Sigma^*)$ via the transition graph: $(v, w) \in R \iff v, w$ end up in the same state. Then, the R -automata is exactly the transition graph. Look at the SCC $Q := \{1, 2, 3\}$. Q has two loops $P_1 := \{1, 2\}$ and $P_2 := Q$, where $P_1 \subsetneq P_2$. Thus, $\mathcal{L}(R)$ is not *infinity-postfix-independent*. Let \tilde{L} be the language accepted by the R -Muller-automaton which only accepts the loop P_1 . Then, \tilde{L} is not recognizable by a deterministic Büchi automaton. Thus, we also have $\text{BC} \lim \mathcal{L}(R) \neq \lim \mathcal{L}(R)$.

The R -Muller-automaton only accepting P_2 is equivalent to the R -Büchi-automaton only accepting state 3. The R -Muller-automaton accepting both P_1 and P_2 is equivalent to the R -Büchi-automaton accepting Q .

All other R -Büchi-automata can be constructed canonically from that. Thus we have

$$\text{BC lim } \mathcal{L}(R) \cap \text{lim } \mathcal{L}^*(\text{reg}) = \text{lim } \mathcal{L}(R).$$

□

However, if we get stricter on the possible subloops, we can show the inequality.

Definition 3.44. Let R be a congruence relation with a finite number of equivalence classes.

If there is a SCC $Q \subseteq S_R$ including two loops $P_1, P_2 \subseteq Q$, $P_1 \neq P_2$ with $P_1 \not\subseteq P_2$, $P_2 \not\subseteq P_1$, then call $\mathcal{L}(R)$ **postfix-loop-deterministic**.

Lemma 3.45. Let R be a congruence relation with a finite number of equivalence classes. And let $\mathcal{L}(R)$ be postfix-loop-deterministic. Then

$$\text{BC lim } \mathcal{L}(R) \cap \text{lim } \mathcal{L}^*(\text{reg}) \neq \text{lim } \mathcal{L}(R).$$

Proof. There is a SCC $Q \subseteq S_R$ including two loops $P_1, P_2 \subseteq Q$, $P_1 \neq P_2$ with $P_1 \not\subseteq P_2$ and $P_2 \not\subseteq P_1$. They are in the same SCC Q , thus there is an outer loop $P \subseteq Q$ with $P_1, P_2 \subseteq P$. In the R -Muller-automaton, let P be the only final state set. Let \tilde{L} be the language accepted by this. For every $q \in Q$, look at the R -Büchi-automaton where q is the only final state. The intersection of all these is recognized by a deterministic Büchi automaton (lemma 2.6). And the intersection accepts exactly \tilde{L} . Thus, $\tilde{L} \in \text{BC lim } \mathcal{L}(R) \cap \text{lim } \mathcal{L}^*(\text{reg})$. However, there is no way in the R -Büchi-automaton to mark a subset of Q as the final states such that we accept \tilde{L} . Thus, $\tilde{L} \notin \text{lim } \mathcal{L}(R)$. □

Now, the question arises whether *postfix-loop-determinism* is equivalent to the inequality.

Lemma 3.46. Let $\mathcal{L}(R)$ be not postfix-loop-deterministic. Then

$$\text{BC lim } \mathcal{L}(R) \cap \text{lim } \mathcal{L}^*(\text{reg}) = \text{lim } \mathcal{L}(R).$$

Proof. For all SCC Q and subloops $P_1, P_2 \subseteq Q$, we either have $P_1 = P_2$ or $P_1 \subseteq P_2$ or $P_2 \subseteq P_1$. If we have always $P_1 = P_2$ for this Q , it means that Q has only one loop. Then, if an R -Muller-automaton accepts Q , we can just mark any state $q \in Q$ final in a R -Büchi-automaton and every α going through Q would be accepted by the R -Büchi-automata exactly if it would be accepted by the R -Muller-automata.

Now, assume that there is $P_1 \subseteq P_2$. If R -Muller would accept P_1 but not P_2 , the resulting language would not be recognizable by deterministic Büchi automata, thus we would be out of $\lim \mathcal{L}^*(\text{reg})$. If R -Muller accepts P_2 but not P_1 , we mark some state from $P_2 - P_1$ as final in the R -Büchi automaton. If it accepts both, we mark some state from P_1 as final in the R -Büchi. In either case, we are in $\lim \mathcal{L}(R)$. If there are other loops $P' \subseteq Q$, they are either supersets of P_2 or subsets of P_1 and thus we can use the same argumentation.

We showed that for all SCC of the R -automata. Thus we have shown the claimed equality. \square

Thus, we get the final result

Theorem 3.47. $\mathcal{L}(R)$ is not postfix-loop-deterministic exactly if and only if

$$\text{BC} \lim \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(R).$$

Proof. Lemma 3.45 and lemma 3.46. \square

Note this is almost equivalent to the dual case:

Lemma 3.48. Let \mathcal{L} be any arbitrary language class which is closed under negation. And let

$$\text{BC} \lim \mathcal{L} \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}.$$

Then we also have

$$\text{BC} \lim \mathcal{L} \cap \widehat{\lim} \mathcal{L}^*(\text{reg}) = \widehat{\lim} \mathcal{L}.$$

Proof.

$$\begin{aligned}
L &\in \text{BC lim } \mathcal{L} \cap \widehat{\text{lim}} \mathcal{L}^*(\text{reg}) \\
&\Leftrightarrow -L \in \text{BC lim } \mathcal{L} \cap \text{lim } \mathcal{L}^*(\text{reg}) \\
&\Leftrightarrow -L \in \text{lim } \mathcal{L} \\
&\Leftrightarrow L \in \widehat{\text{lim}} \mathcal{L}
\end{aligned}$$

□

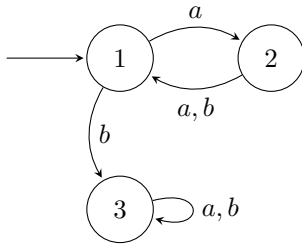

Now, we want to formulate another proof of the generalized Staiger-Wagner equality for $\mathcal{L}(R)$, i.e. $\text{lim} \cap \widehat{\text{lim}} \mathcal{L}(R) = \text{BC ext } \mathcal{L}(R)$ in theorem 3.50. When using the non-postfix-loop-determinism, we can apply the previous results. We will see that we still need the inclusion $\text{BC ext } \mathcal{L}(R) \subseteq \text{BC lim } \mathcal{L}(R)$.

Note that neither infinity-postfix-independence nor non-postfix-loop-determinism give us $\text{ext } \mathcal{L}(R) \subseteq \text{lim } \mathcal{L}(R)$:

Example 3.49. *There is a congruence relation R such that $\mathcal{L}(R)$ is infinity-postfix-independent and not postfix-loop-deterministic and*

$$\text{ext } \mathcal{L}(R) \not\subseteq \text{lim } \mathcal{L}(R).$$

Proof. Let $\Sigma = \{a, b\}$. Consider the congruence relation R defined by the transition graph:

The SCC $\{1, 2\}$ in the R -automaton (re-using the states from the transition graph above) has the loops $\{1, 2\}$. The SCC $\{3\}$ has only itself as its loops. Thus, $\mathcal{L}(R)$ is infinity-postfix-independent and not postfix-loop-deterministic.

However, $L_1 := a(\Sigma a)^* \in \mathcal{L}(R)$ (all words accepted by state 1) but $L_1 \Sigma^* = a \Sigma^* \notin \mathcal{L}(R)$. I.e. $\mathcal{L}(R)$ is not closed under suffix-independence.

Esp. $\text{ext } L_1 = a \Sigma^\omega \notin \text{BC lim } \mathcal{L}(R)$.

Every possible loop in this R -automaton can be expressed by an A - R -automaton. Thus, in this example, we even have

$$\text{BC lim } \mathcal{L}(R) \subsetneq \text{BC ext } \mathcal{L}(R).$$

□

Theorem 3.50. *Let $\mathcal{L}(R)$ be not postfix-loop-deterministic. And let $\text{BC ext } \mathcal{L}(R) \subseteq \text{BC lim } \mathcal{L}(R)$. Then*

$$\lim \cap \widehat{\lim} \mathcal{L}(R) = \text{BC ext } \mathcal{L}(R)$$

Proof. Because $\mathcal{L}(R)$ is closed under change of final states, we can apply theorem 3.20 and have

$$\lim \cap \widehat{\lim} \mathcal{L}(R) \subseteq \text{BC ext } \mathcal{L}(R).$$

Via theorem 3.47, we have

$$\lim \mathcal{L}(R) = \text{BC lim } \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}).$$

Via lemma 3.48, we have

$$\widehat{\lim} \mathcal{L}(R) = \text{BC lim } \mathcal{L}(R) \cap \widehat{\lim} \mathcal{L}^*(\text{reg}).$$

Thus,

$$\lim \cap \widehat{\lim} \mathcal{L}(R) = \text{BC lim } \mathcal{L}(R) \cap \lim \mathcal{L}^*(\text{reg}) \cap \widehat{\lim} \mathcal{L}^*(\text{reg}).$$

With theorem 3.19, we get

$$\lim \cap \widehat{\lim} \mathcal{L}(R) = \text{BC lim } \mathcal{L}(R) \cap \text{BC ext } \mathcal{L}^*(\text{reg}).$$

We have

$$\text{BC ext } \mathcal{L}(R) \subseteq \text{BC lim } \mathcal{L}(R)$$

and

$$\text{BC ext } \mathcal{L}(R) \subseteq \text{BC ext } \mathcal{L}^*(\text{reg}).$$

Thus, we have

$$\text{BC ext } \mathcal{L}(R) \subseteq \text{BC lim } \mathcal{L}(R) \cap \text{BC ext } \mathcal{L}^*(\text{reg}) = \lim \cap \widehat{\lim} \mathcal{L}(R).$$

This gives us the equality. □

Another remark:

Lemma 3.51. *Let $\mathcal{L}(R)$ be closed under suffix-independence. Then, every loop in the R -automaton has only a single state. This also means that $\mathcal{L}(R)$ is not postfix-loop-deterministic and infinity-postfix-independent.*

Proof. By contradiction: Assume there is a loop S with at least two states $q_1, q_2 \in S$. One of those states is reached first by some word. Without restriction, let $w \in \Sigma^*$ so that we reach q_1 but not visit q_2 on the way. Let L_1 be the language of all words which reach q_1 and let L_2 be the language of all words which reach q_2 .

Clearly, $L_2 \in \mathcal{L}(R)$. $\mathcal{L}(R)$ is closed under suffix-independence, thus $L'_2 := L_2 \Sigma^* \in \mathcal{L}(R)$. It means that we reach q_2 and then anything can follow. I.e. any possible following state will accept. I.e. q_1 accepts. This means that $w \in L'_2$. But that is a contradiction because w would not have visited q_2 which was required by L'_2 .

Thus, every loop has only a single state. □

Thus, if $\mathcal{L}(R)$ is closed under suffix-independence, we can directly apply theorem 3.50 and we get $\lim \cap \widehat{\lim} \mathcal{L}(R) = \text{BC ext } \mathcal{L}(R)$. However, as we have also seen in lemma 3.51, this seems like a very strong property.

Chapter 4

Results on concrete *-language classes

In chapter 2, we already showed many results for the different ω -language classes constructed based on $\mathcal{L}^*(\text{reg})$. Mainly, those are the strict inclusions as shown in the diagram in section 2.5.

In chapter 3, we found some general conditions on arbitrary *-language classes \mathcal{L} under which the inclusion diagram stays the same. We also gave other conditions on \mathcal{L} under which the diagram becomes different or other properties change.

We will now study some concrete well-known *-language classes and try to apply the results from chapter 3 as well as study some properties individually.

4.1 Starfree regular languages

The set of **starfree *-languages** $\mathcal{L}(\text{starfree})$ is defined as the smallest set $\mathcal{L} = \mathcal{L}(\text{starfree})$ with

- (a) $\{a\} \in \mathcal{L}$ for all $a \in \Sigma$,
- (b) \mathcal{L} is closed under boolean combinations,
- (c) \mathcal{L} is closed under concatenation.

See [Pin83, Section 2.2] for further references.

Lemma 4.1.

$$\mathcal{L}(\text{starfree}) \subsetneq \mathcal{L}^*(\text{reg})$$

Proof. Obviously, all starfree *-languages are regular. $(\Sigma\Sigma)^*$ is a language which is not starfree (see [Str94, IV.2.1]). Intuitively, this language is counting the letters and requires that the amount is even. Every "counting" language is not starfree. \square

Starfree languages have a direct representing regular expression, directly derived from the definition, like $\neg(a \wedge b)$, i.e. $\neg(\{a\} \cap \{b\})$. However, they don't require that a straightforward (\approx deterministic) representing regular languages also have no stars; for the given example, that is $\neg\emptyset = \Sigma^*$. Thus, $\emptyset, \Sigma, \Sigma^*, \Sigma^+ = \Sigma^* \cdot \Sigma, \{\epsilon\} = \Sigma^* - \Sigma^+, a^* = \Sigma^* - (\Sigma^* \cdot (\Sigma - \{a\}) \cdot \Sigma^*)$ are all starfree languages.

In [Tho96, Theorem 4.10], we can see that

$$\mathcal{L}(\text{starfree}) = \mathcal{L}(\text{FO}[\prec]).$$

In [MP71], the structure of automata accepting starfree languages was studied. The result was that a language L is starfree exactly iff the minimal deterministic automaton for L is counter-free as defined in the following.

Definition 4.2. Let $\mathcal{A} = (Q, \Sigma, q_0, \delta, F)$ be an automaton. A state-sequence $s \in Q^{\geq 2}$ with $s[i] \neq s[j]$ for $i \neq j$ is a **counter** iff there is a $w \in \Sigma^*$ such that

$$\delta(s[i], w) = s[i+1] \quad \forall i < |s|,$$

$$\delta(s[|s|], w) = s[0].$$

If \mathcal{A} has no counter, it is **counter-free**.

First, we start with some specific study on this language class.

Theorem 4.3.

$$\mathcal{L}^\omega(\text{FO}[\prec]) = \text{BC} \lim \mathcal{L}^*(\text{FO}[\prec])$$

Proof. Let $\varphi \in \text{FO}[\prec]$. By the [Tho81, Normal Form Theorem (4.4)] there are bounded formulas $\varphi_1(y), \dots, \varphi_r(y), \psi_1(y), \dots, \psi_r(y)$ such that for all $\alpha \in \Sigma^\omega$:

$$\alpha \models \varphi \Leftrightarrow \alpha \models \bigvee_{i=1}^r (\forall x \exists y > x: \varphi_i(y)) \wedge \neg (\forall x \exists y > x: \psi_i(y))$$

Thus:

$$\begin{aligned} \alpha \models \varphi &\Leftrightarrow \bigvee_{i=1}^r (\underbrace{\alpha \models \forall x \exists y > x: \varphi_i(y)}_{\Leftrightarrow \forall x \exists y > x: \alpha[0, n] \models \varphi_i(\omega)}) \wedge \neg (\alpha \models \forall x \exists y > x: \psi_i(y)) \\ &\Leftrightarrow \exists^\omega n: \alpha[0, n] \models \varphi_i(\omega) \\ &\Leftrightarrow \alpha \in \lim L^*(\varphi_i(\omega)) \end{aligned}$$

where $\varphi_i(\omega)$ stands for φ_i with all bounds removed. I.e. we have

$$L^\omega(\varphi) = \bigcup_{i=1}^r \lim(L^*(\varphi_i(\omega)) \cap \neg \lim(L^*(\psi_i(\omega))),$$

and thus

$$L^\omega(\varphi) \in \text{BC lim } \mathcal{L}^*(\text{FO}[<]).$$

We have proved the \subseteq -direction. For \supseteq :

$$\begin{aligned} \alpha &\in \lim(L^*(\varphi)) \\ \Leftrightarrow \exists^\omega n: \alpha[0, n] \models \varphi \\ \Leftrightarrow \alpha \models \forall x \exists y > x: \varphi(y) \\ \Leftrightarrow \alpha &\in L^\omega(\forall \exists y > x: \varphi(y)) \end{aligned}$$

where $\varphi(y)$ stands for φ with all variables bounded by y . I.e.

$$\lim \mathcal{L}^*(\text{FO}[<]) \subseteq \mathcal{L}^\omega(\text{FO}[<]),$$

and thus also

$$\text{BC lim } \mathcal{L}^*(\text{FO}[<]) \subseteq \mathcal{L}^\omega(\text{FO}[<]).$$

Thus we have proved the equality. \square

Theorem 4.4.

$$\text{BC ext } \mathcal{L}^*(\text{FO}[<]) \subsetneq \text{BC lim } \mathcal{L}^*(\text{FO}[<])$$

Proof. \subseteq : $L \subset \Sigma^\omega \text{ starfree} \Rightarrow L \Sigma^\omega \in \lim(\mathcal{L}^*(\text{FO}[<]))$

\neq :

$$\begin{aligned} L &:= (\Sigma^* a)^\omega \\ \Rightarrow L &= \lim((\Sigma^* a)^*) \\ \Rightarrow L &= L^\omega(\exists^\omega x : Q_a x) \end{aligned}$$

And we have $L \notin \text{BC ext } \mathcal{L}^*(\text{FO}[<])$. \square

$\{a\} \in \mathcal{L}$. $a\Sigma^* \in \mathcal{L}$, thus $a\Sigma^\omega = \text{ext}(\{a\}) = \widehat{\text{ext}} a\Sigma^*$. I.e. $\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \neq \emptyset$.

$\mathcal{L}^*(\text{starfree})$ is obviously closed under negation, suffix-independence, union and alphabet permutation.

Lemma 4.5. $\mathcal{L}^*(\text{starfree})$ is closed under change of final states.

Proof. Let $L \in \mathcal{L}^*(\text{starfree})$ and let \mathcal{A}_L be the minimal deterministic automaton accepting L . Then \mathcal{A}_L is counterfree. Any change of final states of \mathcal{A}_L keeps the counterfree property. \square

$L_a := \Sigma^* a \in \mathcal{L}$ is an $\text{ext}\text{-}\widehat{\text{ext}}$ -separating and $\text{lim}\text{-}\widehat{\text{lim}}$ -separating language.

Thus, with theorem 3.23, for $\mathcal{L} := \mathcal{L}(\text{starfree})$, we get

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \subsetneq \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subsetneq \text{BC ext } \mathcal{L} = \text{lim} \cap \widehat{\text{lim}} \mathcal{L} \subsetneq \text{lim} \cup \widehat{\text{lim}} \mathcal{L} \subsetneq \text{BC lim } \mathcal{L}.$$

4.2 Languages of dot-depth- n

When we consider the concatenation-depth of the construction of starfree languages, we get a hierarchy. The concatenation-depth is also called the **dot-depth**.

For any $n \in \mathbb{N}_0, r \in \mathbb{N}$, define recursively the set $\mathcal{B}_{n,r}$ of *dot-depth n languages with products of length $\leq r$* :

$$\begin{aligned} \mathcal{B}_{0,r} &:= \text{BC} \{ \{w\} \mid w \in \Sigma^{\leq r} \} \\ \mathcal{B}_{n+1,r} &:= \text{BC} \{ B_1 \cdot \dots \cdot B_r \mid B_i \in \mathcal{B}_{n,r} \} \end{aligned}$$

Then, define the language class of **dot-depth- n**

$$\mathcal{L}(\text{dot-depth-}n) := \bigcup_{r \in \mathbb{N}} \mathcal{B}_{n,r}.$$

By this definition, we get

$$\mathcal{L}(\text{starfree}) = \bigcup_{n \in \mathbb{N}} \mathcal{L}(\text{dot-depth-}n).$$

For references, see [Tho87].

A known result (shown e.g. in [Tho87]) is the strict hierarchy

$$\mathcal{L}(\text{dot-depth-}n) \subsetneq \mathcal{L}(\text{dot-depth-}(n+1)).$$

Also, it was shown in [Tho82] that the dot-depth hierarchy characterizes exactly the **first-order quantifier alternation depth** (of $\text{FO}[<]$ formulas in prenex normal form) hierarchy.

For every $n \in \mathbb{N}_0$, $\mathcal{L}(\text{dot-depth-}n)$ is obviously closed under negation and alphabet permutation. From the construction in section 4.1, we see that $\Sigma^* \in \mathcal{L}(\text{dot-depth-}0)$. Thus, $L_a := \Sigma^* \cdot a \in \mathcal{L}(\text{dot-depth-}1)$. L_a is a $\widehat{\text{ext-ext}}$ -separating and $\widehat{\text{lim-lim}}$ -separating language. Thus, as can be seen in theorem 3.23, for $n \geq 1$, $\mathcal{L} := \mathcal{L}(\text{dot-depth-}n)$, we get

$$\begin{aligned} \widehat{\text{ext}} \cap \widehat{\text{ext}} \mathcal{L} &\subsetneq \widehat{\text{ext}} \cup \widehat{\text{ext}} \mathcal{L} \subsetneq \text{BC } \widehat{\text{ext}} \mathcal{L}, \\ \widehat{\text{lim}} \cap \widehat{\text{lim}} \mathcal{L} &\subsetneq \widehat{\text{lim}} \cup \widehat{\text{lim}} \mathcal{L} \subsetneq \text{BC } \widehat{\text{lim}} \mathcal{L}. \end{aligned}$$

For $\mathcal{L}(\text{dot-depth-}0)$, we get a different result as we see in the following.

Lemma 4.6. *$\mathcal{L}(\text{dot-depth-}0)$ is closed under change of final states and we have*

$$\begin{aligned} \widehat{\text{ext}} \mathcal{L}(\text{dot-depth-}0) &= \widehat{\text{ext}} \mathcal{L}(\text{dot-depth-}0), \\ \widehat{\text{lim}} \mathcal{L}(\text{dot-depth-}0) &= \widehat{\text{lim}} \mathcal{L}(\text{dot-depth-}0). \end{aligned}$$

Proof. Let $w \in \Sigma^*$. Consider $L := \{w\}$ or $L := -\{w\}$. Let $\mathcal{A} = (Q, \Sigma, q_0, \delta, F)$ be a det. automaton for L accepting exactly L . Without restriction, \mathcal{A} has the following properties:

- (1) \mathcal{A} is complete, i.e. the transition path is defined for every word in Σ^* .
- (2) The only loops exist in ending states $E := \{q \in Q \mid \forall a \in \Sigma: \delta(q, a) = q\}$.

Then, given two automata with such properties, the product automata $\overset{\times}{\mathcal{A}}$ also has these properties. Thus, all boolean combinations of such automata keep those properties. That are all possible automata for $\mathcal{L}(\text{dot-depth-}0)$ languages.

Now, let $\mathcal{A} = (Q, \Sigma, q_0, \delta, F)$ be any such automata accepting exactly a language $L \in \mathcal{L}(\text{dot-depth-}0)$. $\widehat{\text{ext}} \mathcal{L} \subseteq \widehat{\text{ext}} \mathcal{L}$ means that we can transform the E-acceptance into A-acceptance. We get this by

$$F_{E \rightarrow A} := F \cup \{q \in Q \mid \text{there is a way from } q \text{ to } F\} \cup \delta(F, \Sigma^*).$$

Because of the property (2) of \mathcal{A} , this will accept the same languages. For the other way around, we get

$$F_{A \rightarrow E} := F \cap E.$$

All modifications of the final state set stays in the same language class, given the above properties. Thus, we have

$$\text{ext } \mathcal{L}(\text{dot-depth-0}) = \widehat{\text{ext } \mathcal{L}(\text{dot-depth-0})}.$$

For Büchi/co-Büchi, we don't need to change the final state set at all because all loops are only in the ending states, thus we always have $\lim L = \widehat{\lim L}$. \square

And also:

Lemma 4.7.

$$\text{BC ext } \mathcal{L}(\text{dot-depth-0}) = \lim \cap \widehat{\lim} \mathcal{L}(\text{dot-depth-0})$$

Proof. Define $\mathcal{L} := \mathcal{L}(\text{dot-depth-0})$.

Let \mathcal{A} be an A-automaton with $L^*(\mathcal{A}) \in \mathcal{L}$ with the properties as in lemma 4.6. Because $\widehat{\text{ext } \mathcal{L}} = \text{BC ext } \mathcal{L}$, $L_A^\omega(\mathcal{A})$ is representing any language from $\text{BC ext } \mathcal{L}$. Then,

$$L_A^\omega(\mathcal{A}) = L_{\text{Büchi}}^\omega(\mathcal{A}) = L_{\text{co-Büchi}}^\omega(\mathcal{A}).$$

I.e.

$$\text{BC ext } \mathcal{L} \subseteq \lim \cap \widehat{\lim} \mathcal{L}.$$

From that, we also see that

$$\lim \cup \widehat{\lim} \mathcal{L} \subseteq \widehat{\text{ext } \mathcal{L}},$$

i.e. esp.

$$\lim \cap \widehat{\lim} \mathcal{L} \subseteq \text{BC ext } \mathcal{L}.$$

\square

Thus, for $\mathcal{L} := \mathcal{L}(\text{dot-depth-0})$ we have

$$\text{ext } \cap \widehat{\text{ext } \mathcal{L}} = \text{ext } \cup \widehat{\text{ext } \mathcal{L}} = \text{BC ext } \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L} = \lim \cup \widehat{\lim} \mathcal{L} = \text{BC lim } \mathcal{L}.$$

4.3 Piecewise testable languages

Let $u, v \in \Sigma^*$. For $n \in \mathbb{N}$, define the congruence relation \simeq_{PT_n} :

$$u \simeq_{\text{PT}_n} v \iff \text{Subwords}_{\leq n}(u) = \text{Subwords}_{\leq n}(v),$$

where

$$\text{Subwords}_{\leq n}(u) := \{w \in \Sigma^{\leq n} \mid w \text{ is a subword of } u\}$$

and w is a **subword** of u for $w, u \in \Sigma^*$ iff there is a subsequence $(s_n)_{n \in \mathbb{N}}$ of $(n)_{n \in \mathbb{N}}$ such that $w = u|_s$.

Define

$$\mathcal{L}(\text{PT}_n) := \mathcal{L}(\simeq_{\text{PT}_n}).$$

Then the class of **piecewise testable languages** is defined as

$$\mathcal{L}(\text{PT}) := \bigcup_{n \in \mathbb{N}} \mathcal{L}(\text{PT}_n).$$

We also have the characterization

$$\mathcal{L}(\text{PT}) = \text{BC} \bigcup_{n \in \mathbb{N}_0, a_i \in \Sigma} \{\Sigma^* a_1 \Sigma^* a_2 \Sigma^* \cdots \Sigma^* a_n \Sigma^*\}.$$

See [Pin83, Section 2.3] for further references.

Lemma 4.8.

$$\mathcal{L}(\text{PT}) \subsetneq \mathcal{L}(\text{starfree})$$

Proof. Let $n \in \mathbb{N}$, $a_i \in \Sigma$. Σ^* and $\{a_i\}$ are starfree. Thus, $\Sigma^* a_1 \Sigma^* a_2 \Sigma^* \cdots \Sigma^* a_n \Sigma^*$ is starfree. And starfree languages are closed under boolean operations. This proves the inclusion.

$\Sigma^* aa \Sigma^*$ is a starfree language which is not piecewise testable. □

Theorem 4.9.

$$\text{BC ext } \mathcal{L}^*(\text{PT}) = \text{BC lim } \mathcal{L}^*(\text{PT})$$

Proof. \subseteq : It is sufficient to show $\text{ext}(\mathcal{L}^*(\text{PT})) \subseteq \text{BC lim } \mathcal{L}^*(\text{PT})$.

By complete induction:

$$\begin{aligned} \text{ext}(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*) &= \Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^\omega = \lim(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*) \\ \text{ext}(\neg(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*)) &= \Sigma^\omega = \lim(\Sigma^*) \\ \text{ext}(\emptyset) &= \emptyset = \lim(\emptyset) \end{aligned}$$

It is sufficient to show negation only for such ground terms because we can always push the negation down.

$$\begin{aligned} \text{ext}(A \cup B) &= \text{ext}(A) \cup \text{ext}(B) \\ \text{ext}(A \cap B) &= \text{ext}(A) \cap \text{ext}(B) \end{aligned}$$

This makes the induction complete.

\supseteq : It is sufficient to show $\lim(\mathcal{L}^*(\text{PT})) \subseteq \text{BC ext } \mathcal{L}^*(\text{PT})$.

$$\begin{aligned} \lim(\emptyset) &= \text{ext}(\emptyset), \quad \lim(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*) = \text{ext}(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*) \quad (\text{see above}) \\ \lim(\neg(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*)) &= \{\alpha \in \Sigma^\omega \mid \exists^\omega n: \alpha[0, n] \notin \Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*\} \\ &= \{\alpha \in \Sigma^\omega \mid \forall n: \alpha[0, n] \notin \Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*\} \\ &= \neg \text{ext}(\Sigma^* a_1 \Sigma^* a_2 \cdots a_n \Sigma^*) \end{aligned}$$

$$\begin{aligned} \lim(A \cup B) &= \{\alpha \in \Sigma^\omega \mid \exists^\omega n: \alpha[0, n] \in A \cup B\} = \lim(A) \cup \lim(B) \\ \lim(A \cap B) &= \{\alpha \in \Sigma^\omega \mid \exists^\omega n: \alpha[0, n] \in A \cap B\} \end{aligned}$$

and because A, B are piece-wise testable

$$= \{\alpha \in \Sigma^\omega \mid \exists n: \forall m > n: \alpha[0, m] \in A \cap B\} = \lim(A) \cap \lim(B)$$

□

$\mathcal{L}(\text{PT}_n)$ is defined via the congruence relation \simeq_{PT_n} . The set of equivalence classes is finite. And we get a canonical \simeq_{PT_n} -automaton which we will call just PT_n -automaton. The state set of such automaton is $S_{\text{PT}_n} := \Sigma^* / \simeq_{\text{PT}_n}$.

Thus, by lemma 3.30, $\mathcal{L}(\text{PT}_n)$ is closed under negation, union, intersection and change of final states.

Lemma 4.10. $\mathcal{L}(\text{PT}_n)$ is closed under suffix-independence.

Proof. Look at some PT_n -automaton \mathcal{A} with final state set $F \subseteq S_{\text{PT}_n}$. Any state in S_{PT_n} describes what letters $M \subseteq \Sigma$ we have seen so far. This can only increase. Thus, there is no way back. Let $F' \subseteq S_{\text{PT}_n}$ be all states from F and all that follow. Then

$$L^*(\mathcal{A}(F')) \cdot \Sigma^* = L^*(\mathcal{A}(F)).$$

□

Obviously, $\mathcal{L}(\text{PT}_n)$ is also closed under alphabet permutation. And $L_a := \Sigma^* a \Sigma^* \in \mathcal{L}(\text{PT}_n)$ is a $\widehat{\text{ext-ext}}$ -separating language.

Thus, via theorem 3.23, for $\mathcal{L} := \mathcal{L}(\text{PT}_n)$, we have

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \subsetneq \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subsetneq \text{BC ext } \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L} \subseteq \lim \cup \widehat{\lim} \mathcal{L} \subseteq \text{BC lim } \mathcal{L}.$$

As we have said, in the PT_n -automaton, there are never transitions back. Thus, all loops in the PT_n -automaton only loop in a single state. Thus,

$$\lim \mathcal{L}(\text{PT}_n) = \widehat{\lim} \mathcal{L}(\text{PT}_n).$$

It follows

$$\lim \cap \widehat{\lim} \mathcal{L}(\text{PT}_n) = \lim \cup \widehat{\lim} \mathcal{L}(\text{PT}_n) = \text{BC lim } \mathcal{L}(\text{PT}_n).$$

Via lemma 3.36, we have

$$\text{BC lim } \mathcal{L}(\text{PT}_n) \cap \text{ext } \mathcal{L}^*(\text{reg}) = \text{ext } \mathcal{L}(\text{PT}_n).$$

$\mathcal{L}(\text{PT}_n)$ is obviously also not *postfix-loop-deterministic*. Thus, with lemma 3.46,

$$\text{BC lim } \mathcal{L}(\text{PT}_n) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(\text{PT}_n).$$

For $\mathcal{L}(\text{PT})$, via theorem 3.16 and L_a , we also have

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L}(\text{PT}) \subsetneq \text{ext} \cup \widehat{\text{ext}} \mathcal{L}(\text{PT}) \subsetneq \text{BC ext } \mathcal{L}(\text{PT}).$$

We also have $\mathcal{L}(\text{PT}_n) \subseteq \mathcal{L}(\text{PT}_{n+1})$ for all $n \in \mathbb{N}$. Thus, we have $\text{op } \mathcal{L}(\text{PT}_n) \subseteq \text{op } \mathcal{L}(\text{PT}_{n+1})$ for $\text{op} \in \{\text{ext}, \widehat{\text{ext}}, \text{BC ext}, \lim, \widehat{\lim}, \text{BC lim}\}$.

From the results so far, for $\mathcal{L} := \mathcal{L}(\text{PT})$, it follows

$$\text{ext} \cap \widehat{\text{ext}} \mathcal{L} \subsetneq \text{ext} \cup \widehat{\text{ext}} \mathcal{L} \subsetneq \text{BC ext } \mathcal{L} = \lim \cap \widehat{\lim} \mathcal{L} = \lim \cup \widehat{\lim} \mathcal{L} = \text{BC lim } \mathcal{L}.$$

To extend that, we note that every loop in a PT_n -automaton is looping only in a single state because we never can get back as it was noted earlier. Thus, by lemma 3.39, $\mathcal{L}(PT_n)$ is *infinity-postfix-independent* (definition 3.38). Also, $\mathcal{L}(PT_n)$ is not *postfix-loop-deterministic* (definition 3.44).

By lemma 3.42 or theorem 3.47, we get

$$BC \lim \mathcal{L}(PT_n) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(PT_n).$$

I.e. we also have

$$BC \lim \mathcal{L}(PT) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(PT).$$

Positive piece-wise testable languages are defined as

$$\mathcal{L}(\text{pos-PT}) := \text{pos-BC} \bigcup_{n \in \mathbb{N}_0, a_i \in \Sigma} \{ \Sigma^* a_1 \Sigma^* a_2 \Sigma^* \cdots \Sigma^* a_n \Sigma^* \},$$

where pos-BC is defined like BC except the negation.

For positive piece-wise testable (pos-PT) languages, we get the same result on the BC ext and BC lim relation.

Theorem 4.11.

$$BC \text{ ext } \mathcal{L}^*(\text{pos-PT}) = BC \lim \mathcal{L}^*(\text{pos-PT})$$

Proof. \subseteq : Exactly like the proof for theorem 4.9 except that we leave out the negated part.

\supseteq : Also like the proof for theorem 4.9. □

We note that we cannot make good reasonings about $\widehat{\text{ext}}$ and $\widehat{\text{lim}}$ because we don't have the negation closure. However, we can define

$$\neg \text{ext } \mathcal{L} := \{ \neg \text{ext } L \mid L \in \mathcal{L} \},$$

$$\neg \text{lim } \mathcal{L} := \{ \neg \text{lim } L \mid L \in \mathcal{L} \}.$$

When using $\neg \text{ext}$ and $\neg \text{lim}$ instead of $\widehat{\text{ext}}$ and $\widehat{\text{lim}}$, we get the extended result

$$BC \text{ ext } \mathcal{L}(\text{pos-PT}) = \lim \cap \neg \text{lim } \mathcal{L}(\text{pos-PT}) = \lim \cup \neg \text{lim } \mathcal{L}(\text{pos-PT}) = BC \lim \mathcal{L}(\text{pos-PT}).$$

Also, the L_a from above is also in $\mathcal{L}(\text{pos-PT})$. When using $\neg \text{ext}$, we don't need the negation closure to use theorem 3.16. Thus, we have

$$\text{ext} \cap \neg \text{ext} \mathcal{L}(\text{pos-PT}) \subsetneq \text{ext} \cup \neg \text{ext} \mathcal{L}(\text{pos-PT}) \subsetneq \text{BC ext } \mathcal{L}(\text{pos-PT}).$$

We also have a relation between pos-PT and PT.

Lemma 4.12.

$$\text{BC ext } \mathcal{L}^*(\text{pos-PT}) = \text{BC ext } \mathcal{L}^*(\text{PT})$$

Proof. In the proof of $\lim \mathcal{L}^*(\text{PT}) \subseteq \text{BC ext } \mathcal{L}^*(\text{PT})$ we actually proved $\text{BC } \lim \mathcal{L}^*(\text{PT}) \subseteq \text{BC ext } \mathcal{L}^*(\text{pos-PT})$. Similiarly we also proved $\text{BC ext } \mathcal{L}^*(\text{PT}) \subseteq \text{BC } \lim \mathcal{L}^*(\text{pos-PT})$.

With theorem 4.9 and theorem 4.11 we get the claimed equality. \square

4.4 Locally testable languages

Let $u, v \in \Sigma^*$. For $n \in \mathbb{N}$, define the congruence relation \simeq_{LT_n} :

$$\begin{aligned} u \simeq_{\text{LT}_n} v & :\Leftrightarrow \begin{aligned} & \text{left-Fact}_{<n}(u) = \text{left-Fact}_{<n}(v), \\ & \text{right-Fact}_{<n}(u) = \text{right-Fact}_{<n}(v), \\ & \text{Fact}_n(u) = \text{Fact}_n(v) \end{aligned} \\ & \Leftrightarrow \begin{aligned} & u \simeq_{\text{endwise}_n} v, \\ & \text{Fact}_n(u) = \text{Fact}_n(v) \end{aligned} \end{aligned}$$

where

$$\begin{aligned} \text{left-Fact}_{<n}(v) & := \{w \in \Sigma^{<n} \mid w \text{ is left-factor of } v\} \\ \text{right-Fact}_{<n}(v) & := \{w \in \Sigma^{<n} \mid w \text{ is right-factor of } v\} \\ \text{Fact}_n(v) & := \{w \in \Sigma^n \mid w \text{ is factor of } v\}. \end{aligned}$$

For $v, w \in \Sigma^*$,

$$\begin{aligned} w \text{ is a \textbf{left-factor} of } v & :\Leftrightarrow \exists u \in \Sigma^* : wu = v \\ w \text{ is a \textbf{right-factor} of } v & :\Leftrightarrow \exists u \in \Sigma^* : uw = v \\ w \text{ is a \textbf{factor} of } v & :\Leftrightarrow \exists u_1, u_2 \in \Sigma^* : u_1 w u_2 = v. \end{aligned}$$

Define

$$\mathcal{L}(\text{LT}_n) := \mathcal{L}(\simeq_{\text{LT}_n}).$$

Then the class of **locally testable languages** is defined as

$$\mathcal{L}(\text{LT}) := \bigcup_{n \in \mathbb{N}} \mathcal{L}(\text{LT}_n).$$

We also have the characterization

$$\mathcal{L}(\text{LT}) = \text{BC} \bigcup_{u, v, w \in \Sigma^+} \{u\Sigma^*, \Sigma^*v, \Sigma^*w\Sigma^*, \{\epsilon\}\}.$$

See [Pin83, Section 2.5] for further references.

We also have more direct connection to starfree languages:

$$\mathcal{L}(\text{LT}) = \mathcal{L}(\text{dot-depth-1})$$

See [Kna76] for references.

Theorem 4.13.

$$\text{BC ext } \mathcal{L}^*(\text{LT}) \subsetneq \text{BC lim } \mathcal{L}^*(\text{LT})$$

Proof. Let $w \in \Sigma^+$.

$$\text{ext}(w\Sigma^*) = \text{lim}(w\Sigma^*)$$

$$\text{ext}(\Sigma^*w) = \Sigma^*w\Sigma^\omega = \text{lim}(\Sigma^*w\Sigma^*)$$

$$\text{ext}(\Sigma^*w\Sigma^*) = \Sigma^*w\Sigma^\omega = \text{lim}(\Sigma^*w\Sigma^*)$$

Thus we have

$$\text{BC ext } \mathcal{L}^*(\text{LT}) \subseteq \text{BC lim } \mathcal{L}^*(\text{LT}).$$

But we also have

$$\text{lim}(\Sigma^*) = (\Sigma^*w)^\omega \notin \text{BC ext } \mathcal{L}^*(\text{LT}).$$

□

$\mathcal{L}(\text{LT}_n)$ is defined via the congruence relation \simeq_{LT_n} . The set of equivalence classes is finite. And we get a canonical \simeq_{LT_n} -automaton which we will call just LT_n -automaton.

Thus, by lemma 3.30, $\mathcal{L}(\text{LT}_n)$ is closed under negation, union, intersection and change of final states.

About the relation to $\mathcal{L}^*(\text{reg})$: Our tools are lemma 3.42 or theorem 3.47.

Lemma 4.14. *Let $a, b \in \Sigma$. $\mathcal{L}(\text{LT}_n)$ is postfix-loop-deterministic (definition 3.44) and not infinity-postfix-independent (definition 3.38) for $n \geq 2$.*

Proof. Let $u \in \Sigma^*$ so that every word in Σ^2 is a factor of u . Then, in the LT_2 -automata, we are in a final SCC S where we cannot get out anymore because all left-factors and all factors are fixed. We can only change the right-factors (of len < 2). The states of S are

$$S = \{\langle wa \rangle, \langle wb \rangle\}.$$

And we have two loops

$$P_1 : \langle wa \rangle \xrightarrow{a} \langle wa \rangle$$

and

$$P_2 : \langle wb \rangle \xrightarrow{b} \langle wb \rangle,$$

where $P_1, P_2 \subseteq S$, $P_1 \neq P_2$ and $P_1 \not\subseteq P_2, P_2 \not\subseteq P_1$. I.e. $\mathcal{L}(\text{LT}_2)$ is postfix-loop-deterministic and not infinity-postfix-independent. This can be extended in a similar way for any $n > 2$. \square

We cannot apply lemma 3.42. But by theorem 3.47, for all $n \geq 2$, we have

$$\text{BC} \lim \mathcal{L}(\text{LT}_n) \cap \lim \mathcal{L}^*(\text{reg}) \supsetneq \lim \mathcal{L}(\text{LT}_n).$$

Unfortunately, we cannot argue directly about $\mathcal{L}(\text{LT})$ with this result.

For LT_1 , it looks different. The right-factors of len < 1 don't tell anything anymore about a word. Thus, $\mathcal{L}(\text{LT}_1)$ is not postfix-loop-deterministic. I.e., by lemma 3.42, we have

$$\text{BC} \lim \mathcal{L}(\text{LT}_1) \cap \lim \mathcal{L}^*(\text{reg}) = \lim \mathcal{L}(\text{LT}_1).$$

Positive locally testable languages are defined as

$$\mathcal{L}(\text{pos-LT}) = \text{pos-BC} \bigcup_{u,v,w \in \Sigma^+} \{u\Sigma^*, \Sigma^*v, \Sigma^*w\Sigma^*, \{\epsilon\}\}.$$

4.5 Locally threshold testable languages

Let $u, v \in \Sigma^*$. Let $k, r \in \mathbb{N}$, define the congruence relation $\simeq_{\text{LTT}_r^k}$:

$$\begin{aligned} u \simeq_{\text{LTT}_r^k} v \quad :\Leftrightarrow \quad & \text{left-Fact}_{<n}(u) = \text{left-Fact}_{<n}(v), \\ & \text{right-Fact}_{<n}(u) = \text{right-Fact}_{<n}(v), \\ & \forall x \in \Sigma^{\leq k} : \text{count-Fact}_x(u) = \text{count-Fact}_x(v) < r \quad \text{or} \\ & \min \{ \text{count-Fact}_x(u), \text{count-Fact}_x(v) \} \geq r \end{aligned}$$

where for $x \in \Sigma^*$, $\text{count-Fact}_x(u)$ states how often x occurs as a factor in u , formally

$$\text{count-Fact}_x(u) := \# \{ n \in \mathbb{N} \mid u[n, n + |x| - 1] = x \}.$$

Define

$$\mathcal{L}(\text{LTT}_r^k) := \mathcal{L}(\simeq_{\text{LTT}_r^k}).$$

Then the class of **locally threshold testable languages** is defined as

$$\mathcal{L}(\text{LTT}) := \bigcup_{k, r \in \mathbb{N}} \mathcal{L}(\text{LTT}_r^k).$$

Locally threshold testable languages are a generalization of locally testable language. We can see that

$$\mathcal{L}(\text{LT}) = \bigcup_{k \in \mathbb{N}} \mathcal{L}(\text{LTT}_1^k).$$

For further references, see [Str94, IV.3].

In [Str94, IV.3.3] or [Tho96, Corollary 4.9], we can see that

$$\mathcal{L}(\text{LTT}) = \mathcal{L}(\text{FO}[+1]).$$

In [Str94, IV.3.4], we see that

$$\mathcal{L}(\text{LTT}) \subsetneq \mathcal{L}(\text{starfree}).$$

Theorem 4.15.

$$\mathcal{L}^\omega(\text{FO}[+1]) = \text{BC ext } \mathcal{L}^*(\text{FO}[+1])$$

Proof. From [Tho96, Theorem 4.8], we know that each formular in $\text{FO}[+1]$ is equivalent (for both finite and infinite words) to a boolean combination of statements “sphere $\sigma \in \Sigma^+$ occurs $\geq n$ times”. That statement can be expressed by a sentence of the form

$$\psi := \exists \bar{x}_1 \cdots \exists \bar{x}_n \varphi(\bar{x}_1, \dots, \bar{x}_n)$$

where each $\overline{x_i}$ is a $|\sigma|$ -tuple of variables and the formula φ states:

$$\bigwedge_{\substack{i,j \in \underline{n}, \\ i \neq j, \\ k,l \in \underline{|\sigma|}}} x_{i,k} \neq x_{j,l} \wedge \bigwedge_{\substack{i \in \underline{n}, \\ k \in \underline{|\sigma|-1}}} x_{i,k+1} = x_{i,k} + 1 \wedge \bigwedge_{\substack{i \in \underline{n}, \\ k \in \underline{|\sigma|}}} Q_{\sigma_k} x_{i,k}$$

For ψ , we have:

$$\alpha \models \psi \Leftrightarrow \exists n: \alpha[0, n] \models \psi \text{ for all } \alpha \in \Sigma^\omega,$$

i.e.

$$L^\omega(\psi) = \text{ext } L^*(\psi).$$

Any formular in FO[+1] can be expressed as a boolean combination of ψ -like formular.

With

$$L^\omega(\neg\psi) = \neg L^\omega(\psi)$$

$$L^\omega(\psi_1 \wedge \psi_2) = L^\omega(\psi_1) \cap L^\omega(\psi_2)$$

$$L^\omega(\psi_1 \vee \psi_2) = L^\omega(\psi_1) \cup L^\omega(\psi_2)$$

we get:

$$\mathcal{L}^\omega(\text{FO}[+1]) = \text{BC ext } \mathcal{L}^*(\text{FO}[+1]).$$

□

4.6 Endwise testable languages

Let $u, v \in \Sigma^*$. For $n \in \mathbb{N}$, define the congruence relation $\simeq_{\text{endwise}_n}$:

$$u \simeq_{\text{endwise}_n} v \iff \begin{aligned} \text{left-Fact}_{<n}(u) &= \text{left-Fact}_{<n}(v), \\ \text{right-Fact}_{<n}(u) &= \text{right-Fact}_{<n}(v) \end{aligned}$$

Then the class of **endwise testable languages** is defined as

$$\mathcal{L}(\text{endwise}) := \bigcup_{n \in \mathbb{N}} \mathcal{L}(\simeq_{\text{endwise}_n}).$$

We also have the characterization

$$\mathcal{L}(\text{endwise}) = \{X\Sigma^*Y \cup Z \mid X, Y \subseteq \Sigma^+, Z \subseteq \Sigma^*, X, Y, Z \text{ finite}\}.$$

See [Pin83, Section 2.4] for further references.

- $\text{BC ext } \mathcal{L}^*(\text{endwise}) \neq \text{BC lim } \mathcal{L}^*(\text{endwise})$ because $\Sigma^* a \in \mathcal{L}^*(\text{endwise})$.
- $\text{ext}(a\Sigma^* a) = a\Sigma^* a\Sigma^\omega \notin \text{BC lim } \mathcal{L}^*(\text{endwise})$

4.7 Finite / Co-finite languages

The class of finite *-languages is denoted by $\mathcal{L}(\text{finite})$. The class of infinite *-languages is denoted by $\mathcal{L}(\text{co-finite})$. Formally

We get the following results:

- $\text{ext } \mathcal{L}(\text{finite}) = \mathcal{L}(\text{finite}) \cdot \Sigma^\omega$
- $\widehat{\text{ext}} \mathcal{L}(\text{finite}) = \{\emptyset\}$
- $\neg \text{ext } \mathcal{L}(\text{finite}) = \{-\text{ext } L \mid L \in \mathcal{L}(\text{finite})\} = \{\widehat{\text{ext}} L \mid L \in \mathcal{L}(\text{co-finite})\} = \widehat{\text{ext}} \mathcal{L}(\text{co-finite})$
- $\text{lim } \mathcal{L}(\text{finite}) = \{\emptyset\}$
- $\widehat{\text{lim}} \mathcal{L}(\text{finite}) = \{\emptyset\}$
- $\neg \text{lim } \mathcal{L}(\text{finite}) = \{\Sigma^\omega\}$
- $\text{BC lim } \mathcal{L}(\text{finite}) = \{\emptyset, \Sigma^\omega\}$
- $\text{ext } \mathcal{L}(\text{co-finite}) = \{\Sigma^\omega\}$
- $\neg \text{ext } \mathcal{L}(\text{co-finite}) = \{\emptyset\}$
- $\text{BC ext } \mathcal{L}(\text{co-finite}) = \{\emptyset, \Sigma^\omega\}$
- $\text{lim } \mathcal{L}(\text{co-finite}) = \{\Sigma^\omega\}$
- $\widehat{\text{lim}} \mathcal{L}(\text{co-finite}) = \{\Sigma^\omega\}$
- $\neg \text{lim } \mathcal{L}(\text{co-finite}) = \widehat{\text{lim}} \mathcal{L}(\text{finite}) = \{\emptyset\}$
- $\text{BC lim } \mathcal{L}(\text{co-finite}) = \{\emptyset, \Sigma^\omega\}$

Thus, the usual inclusions don't hold at all here. Esp. we again have

$$\text{BC ext } \mathcal{L}(\text{finite}) \supsetneq \text{BC lim } \mathcal{L}(\text{finite}), \quad \text{BC ext } \mathcal{L}(\text{co-finite}) = \text{BC lim } \mathcal{L}(\text{co-finite}).$$

We also have

$$\text{BC ext } \mathcal{L}(\text{co-finite}) = \text{BC lim } \mathcal{L}(\text{finite}) = \text{BC lim } \mathcal{L}(\text{co-finite}).$$

4.8 Local languages

A language $L \subseteq \Sigma^*$ is called **local** iff there exist $P, S \subseteq \Sigma, N \subseteq \Sigma^2$ such that

$$L - \{\epsilon\} = (P\Sigma^* \cap \Sigma^*S) - (\Sigma^*N\Sigma^*).$$
